Package 'SimDesign'

April 24, 2024

Title Structure for Organizing Monte Carlo Simulation Designs

Version 2.15.1

Description Provides tools to safely and efficiently organize and execute

Monte Carlo simulation experiments in R.

The package controls the structure and back-end of Monte Carlo simulation experiments by utilizing a generate-analyse-summarise workflow. The workflow safeguards against common simulation coding issues, such as automatically re-simulating non-convergent results, prevents inadvertently overwriting simulation files, catches error and warning messages during execution, implicitly supports parallel processing with high-quality random number generation, and provides tools for managing high-performance computing (HPC) array jobs submitted to schedulers such as SLURM. For a pedagogical introduction to the package see Sigal and Chalmers (2016) <doi:10.1080/10691898.2016.1246953>. For a more indepth overview of

the package and its design philosophy see Chalmers and Adkins (2020) <doi:10.20982/tqmp.16.4.p248>.

add_missing

Add missing values to a vector given a MCAR, MAR, or MNAR scheme

Description

Given an input vector, replace elements of this vector with missing values according to some scheme. Default method replaces input values with a MCAR scheme (where on average 10% of the values will be replaced with NAs). MAR and MNAR are supported by replacing the default FUN argument.

Usage

```
add_missing(y, fun = function(y, rate = 0.1, ...) rep(rate, length(y)), ...)
```

Arguments

y an input vector that should contain missing data in the form of NA's

fun a user defined function indicating the missing data mechanism for each element in y. Function must return a vector of probability values with the length equal to the length of y. Each value in the returned vector indicates the probability that the respective element in y will be replaced with NA. Function must contain the argument y, representing the input vector, however any number of additional arguments can be included

. . . additional arguments to be passed to FUN

4 add_missing

Details

Given an input vector y, and other relevant variables inside (X) and outside (Z) the data-set, the three types of missingness are:

- **MCAR** Missing completely at random (MCAR). This is realized by randomly sampling the values of the input vector (y) irrespective of the possible values in X and Z. Therefore missing values are randomly sampled and do not depend on any data characteristics and are truly random
- **MAR** Missing at random (MAR). This is realized when values in the dataset (X) predict the missing data mechanism in y; conceptually this is equivalent to P(y = NA|X). This requires the user to define a custom missing data function
- **MNAR** Missing not at random (MNAR). This is similar to MAR except that the missing mechanism comes from the value of y itself or from variables outside the working dataset; conceptually this is equivalent to P(y=NA|X,Z,y). This requires the user to define a custom missing data function

Value

the input vector y with the sampled NA values (according to the FUN scheme)

aggregate_simulations 5

```
fun <- function(y, X, ...){</pre>
    p <- rep(0, length(y))</pre>
    p[X\$group == 'female' \& X\$level == 'low'] <- .2
}
ymiss <- add_missing(y, X, fun=fun)</pre>
tail(cbind(ymiss, X), 10)
## missingness as a function of elements in X (i.e., a type of MAR)
fun <- function(y, X){</pre>
   \# missingness with a logistic regression approach
   df <- data.frame(y, X)</pre>
   mm <- model.matrix(y ~ group + level, df)</pre>
   cfs <- c(-5, 2, 3) #intercept, group, and level coefs
   z <- cfs %*% t(mm)
   plogis(z)
}
ymiss <- add_missing(y, X, fun=fun)</pre>
tail(cbind(ymiss, X), 10)
## missing values when y elements are large (i.e., a type of MNAR)
fun <- function(y) ifelse(abs(y) > 1, .4, \emptyset)
ymiss <- add_missing(y, fun=fun)</pre>
tail(cbind(y, ymiss), 10)
## End(Not run)
```

aggregate_simulations Collapse separate simulation files into a single result

Description

This function aggregates the results from SimDesign's runSimulation into a single objects suitable for post-analyses, or combines all the saved results directories and combines them into one. This is useful when results are run piecewise on one node (e.g., 500 replications in one batch, 500 again at a later date) or run independently across different nodes/computers that are not on the same network.

Usage

```
aggregate_simulations(
  files = NULL,
  filename = NULL,
  dirs = NULL,
  results_dirname = "SimDesign_aggregate_results",
  select = NULL,
```

```
check.only = FALSE,
  target.reps = NULL
)
```

Arguments

files a character vector containing the names of the simulation's final .rds files

filename (optional) name of .rds file to save aggregate simulation file to. If not specified

then the results will only be returned in the R console

dirs a character vector containing the names of the save_results directories to be

aggregated. A new folder will be created and placed in the results_dirname

output folder

results_dirname

the new directory to place the aggregated results files

select a character vector indicating columns to variables to select from the SimExtract(what='results')

information. This is mainly useful when RAM is an issue given simulations with many stored estimates. Default includes the results objects in their entirety, though to omit all internally stored simulation results pass the character 'NONE'

check.only logical; for larger simulations file sets, such as those generated by runArraySimulation,

return the design conditions that do no satisfy the target.reps

target.reps (optional) number of replications to check against to evaluate whether the sim-

ulation files returned the desired number of replications. If missing, the highest detected value from the collected set of replication information will be used

Value

if files is used the function returns a data.frame/tibble with the (weighted) average of the simulation results. Otherwise, if dirs is used, the function returns NULL

sim
## End(Not run)
```

Analyse 9

Description

Compute all relevant test statistics, parameter estimates, detection rates, and so on. This is the computational heavy lifting portion of the Monte Carlo simulation. Users may define a single Analysis function to perform all the analyses in the same function environment, or may define a list of named functions to runSimulation to allow for a more modularized approach to performing the analyses in independent blocks (but that share the same generated data). Note that if a suitable Generate function was not supplied then this function can be used to be generate and analyse the Monte Carlo data (though in general this setup is not recommended for larger simulations).

Usage

```
Analyse(condition, dat, fixed_objects = NULL)
```

Arguments

condition a single row from the design input (as a data.frame), indicating the simulation

conditions

dat the dat object returned from the Generate function (usually a data.frame,

matrix, vector, or list)

fixed_objects object passed down from runSimulation

Details

In some cases, it may be easier to change the output to a named list containing different parameter configurations (e.g., when determining RMSE values for a large set of population parameters).

The use of try functions is generally not required in this function because Analyse is internally wrapped in a try call. Therefore, if a function stops early then this will cause the function to halt internally, the message which triggered the stop will be recorded, and Generate will be called again to obtain a different dataset. That said, it may be useful for users to throw their own stop commands if the data should be re-drawn for other reasons (e.g., an estimated model terminated correctly but the maximum number of iterations were reached).

Value

returns a named numeric vector or data.frame with the values of interest (e.g., p-values, effects sizes, etc), or a list containing values of interest (e.g., separate matrix and vector of parameter estimates corresponding to elements in parameters). If a data.frame is returned with more than 1 row then these objects will be wrapped into suitable list objects

```
stop, AnalyseIf, convertWarnings
```

Examples

```
## Not run:
analyse <- function(condition, dat, fixed_objects = NULL) {</pre>
   # require packages/define functions if needed, or better yet index with the :: operator
    require(stats)
    mygreatfunction <- function(x) print('Do some stuff')</pre>
    #wrap computational statistics in try() statements to control estimation problems
    welch <- t.test(DV ~ group, dat)</pre>
    ind <- stats::t.test(DV ~ group, dat, var.equal=TRUE)</pre>
    # In this function the p values for the t-tests are returned,
    # and make sure to name each element, for future reference
    ret <- c(welch = welch$p.value,
             independent = ind$p.value)
    return(ret)
}
# A more modularized example approach
analysis_welch <- function(condition, dat, fixed_objects = NULL) {</pre>
   welch <- t.test(DV ~ group, dat)</pre>
    ret <- c(p=welch$p.value)</pre>
    ret
}
analysis_ind <- function(condition, dat, fixed_objects = NULL) {</pre>
    ind <- t.test(DV ~ group, dat, var.equal=TRUE)</pre>
    ret <- c(p=ind$p.value)</pre>
   ret
}
# pass functions as a named list
# runSimulation(..., analyse=list(welch=analyse_welch, independent=analysis_ind))
## End(Not run)
```

AnalyseIf

Perform a test that indicates whether a given Analyse() function should be executed

AnalyseIf 11

Description

This function is designed to prevent specific analysis function executions when the design conditions are not met. Primarily useful when the analyse argument to runSimulation was input as a named list object, however some of the analysis functions are not interesting/compatible with the generated data and should therefore be skipped.

Usage

```
AnalyseIf(x, condition = NULL)
```

Arguments

x logical statement to evaluate. If the statement evaluates to TRUE then the remainder of the defined function will be evaluated

der of the defined function will be evaluated

condition (optional) the current design condition. This does not need to be supplied if the

expression in x evaluates to valid logical (e.g., use Attach(condition) prior to using AnalyseIf, or use with(condition, AnalyseIf(someLogicalTest)))

## End(Not run)
```

Attach

Attach objects for easier reference

Description

The behaviour of this function is very similar to attach, however it is environment specific, and therefore only remains defined in a given function rather than in the Global Environment. Hence, this function is much safer to use than the attach, which incidentally should never be used in your code. This is useful primarily as a convenience function when you prefer to call the variable names in condition directly rather than indexing with condition\$sample_size or with(condition, sample_size), for example.

Usage

```
Attach(
...,
omit = NULL,
```

Attach 13

```
check = TRUE,
  attach_listone = TRUE,
  RStudio_flags = FALSE
)
```

Arguments

... a comma separated list of data.frame, tibble, list, or matrix objects con-

taining (column) elements that should be placed in the current working environ-

ment

omit an optional character vector containing the names of objects that should not be

attached to the current environment. For instance, if the objects named 'a' and 'b' should not be attached then use omit = c('a', 'b'). When NULL (default)

all objects are attached

check logical; check to see if the function will accidentally replace previously defined

variables with the same names as in condition? Default is TRUE, which will

avoid this error

attach_listone logical; if the element to be assign is a list of length one then assign the first

element of this list with the associated name. This generally avoids adding an

often unnecessary list 1 index, such as name <- list[[1L]]

RStudio_flags logical; print R script output comments that disable flagged missing variables in

RStudio? Requires the form Attach(Design, RStudio_flags=TRUE) or in an interactive debugging session Attach(condition, RStudio_flags=TRUE)

Details

Note that if you are using RStudio with the "Warn if variable used has no definition in scope" diagnostic flag then using Attach() will raise suspensions. To suppress such issues, you can either disable such flags (the atomic solution) or evaluate the following output in the R console and place the output in your working simulation file.

```
Attach(Design, RStudio_flags = TRUE)
```

Examples

```
## Not run:
data(BF_sim_alternative)
head(BF_sim_alternative)

#' #Type I errors
subset(BF_sim_alternative, var_ratio == 1)
## End(Not run)
```

bias

Compute (relative/standardized) bias summary statistic

Description

Computes the (relative) bias of a sample estimate from the parameter value. Accepts estimate and parameter values, as well as estimate values which are in deviation form. If relative bias is requested the estimate and parameter inputs are both required.

bias 17

Usage

```
bias(
   estimate,
   parameter = NULL,
   type = "bias",
   abs = FALSE,
   percent = FALSE,
   unname = FALSE
)
```

Arguments

estimate

a numeric vector, matrix/data.frame, or list of parameter estimates. If a vector, the length is equal to the number of replications. If a matrix/data.frame, the number of rows must equal the number of replications. list objects will be looped over using the same rules after above after first translating the information into one-dimensional vectors and re-creating the structure upon return

parameter

a numeric scalar/vector indicating the fixed parameters. If a single value is supplied and estimate is a matrix/data. frame then the value will be recycled for each column; otherwise, each element will be associated with each respective column in the estimate input. If NULL then it will be assumed that the estimate input is in a deviation form (therefore mean(estimate)) will be returned)

type

type of bias statistic to return. Default ('bias') computes the standard bias (average difference between sample and population), 'relative' computes the relative bias statistic (i.e., divide the bias by the value in parameter; note that multiplying this by 100 gives the "percent bias" measure, or if Type I error rates (α) are supplied will result in the "percentage error"), 'abs_relative' computes the relative bias but the absolute values of the parameters are used in the denominator rather than the (potentially) signed input values, and 'standardized' computes the standardized bias estimate (standard bias divided by the standard deviation of the sample estimates)

abs

logical; find the absolute bias between the parameters and estimates? This effectively just applies the abs transformation to the returned result. Default is FALSE

percent

logical; change returned result to percentage by multiplying by 100? Default is FALSE

unname

logical; apply unname to the results to remove any variable names?

Value

returns a numeric vector indicating the overall (relative/standardized) bias in the estimates

```

boot_predict

Compute prediction estimates for the replication size using bootstrap MSE estimates

Description

This function computes bootstrap mean-square error estimates to approximate the sampling behavior of the meta-statistics in SimDesign's summarise functions. A single design condition is supplied, and a simulation with max(Rstar) replications is performed whereby the generate-analyse results are collected. After obtaining these replication values, the replications are further drawn from (with replacement) using the differing sizes in Rstar to approximate the bootstrap MSE behavior given different replication sizes. Finally, given these bootstrap estimates linear regression models are fitted using the predictor term one_sqrtR = 1 / sqrt(Rstar) to allow extrapolation to replication sizes not observed in Rstar. For more information about the method and subsequent bootstrap MSE plots, refer to Koehler, Brown, and Haneuse (2009).

Usage

```
boot_predict(
  condition,
  generate,
  analyse,
  summarise,
  fixed_objects = NULL,
   ...,
  Rstar = seq(100, 500, by = 100),
  boot_draws = 1000
)
```

Arguments

condition a data. frame consisting of one row from the original design input object used

within runSimulation

generate see runSimulation analyse see runSimulation summarise see runSimulation fixed_objects see runSimulation

... additional arguments to be passed to runSimulation

Rstar a vector containing the size of the bootstrap subsets to obtain. Default investi-

gates the vector [100, 200, 300, 400, 500] to compute the respective MSE terms

boot_draws number of bootstrap replications to draw. Default is 1000

20 boot_predict

Value

returns a list of linear model objects (via lm) for each meta-statistics returned by the summarise() function

Bradley1978

Bradley's (1978) empirical robustness interval

Description

Robustness interval criteria for empirical detection rate estimates and empirical coverage estimates defined by Bradley (1978). See EDR and ECR to obtain such estimates.

Usage

```
Bradley1978(
  rate,
  alpha = 0.05,
  type = "liberal",
  CI = FALSE,
  out.logical = FALSE,
  out.labels = c("conservative", "robust", "liberal"),
  unname = FALSE
)
```

Arguments

rate

(optional) numeric vector containing the empirical detection rate(s) or empirical confidence interval estimates. If supplied a character vector with elements de-

22 Bradley1978

fined in out.labels or a logical vector will be returned indicating whether the detection rate estimate is considered 'robust'.

When the input is an empirical coverage rate the argument CI must be set to

TRUE.

If this input is missing, the interval criteria will be printed to the console

alpha Type I error rate to evaluated (default is .05)

type character vector indicating the type of interval classification to use. Default is

'liberal', however can be 'stringent' to use Bradley's more stringent robustness

criteria

CI logical; should this robust interval be constructed on empirical detection rates

(FALSE) or empirical coverage rates (TRUE)?

out.logical logical; should the output vector be TRUE/FALSE indicating whether the sup-

plied empirical detection rate/CI should be considered "robust"? Default is

FALSE, in which case the out.labels elements are used instead

out.labels character vector of length three indicating the classification labels according to

the desired robustness interval

unname logical; apply unname to the results to remove any variable names?

CC

Compute congruence coefficient

Description

Computes the congruence coefficient, also known as an "unadjusted" correlation or Tucker's congruence coefficient.

Usage

```
CC(x, y = NULL, unname = FALSE)
```

Arguments

x a vector or data. frame/matrix containing the variables to use. If a vector then

the input y is required, otherwise the congruence coefficient is computed for all

bivariate combinations

y (optional) the second vector input to use if x is a vector

unname logical; apply unname to the results to remove any variable names?

convertWarnings

Wrapper to convert all/specific warning messages to errors

Description

Function is intended to be a message converter for functions that are known to throw warning messages that should generally be treated as errors instead (e.g., non-positive definite matrix warnings, negative variance estimate warnings, etc). Specific warning messages can be caught if specified, otherwise all detected warning messages will be converted to errors for the evaluated R expression.

Usage

```
convertWarnings(expr, warning2error = NULL, muffle = FALSE)
```

Arguments

expression to be evaluated (e.g., ret <- myfun(args) should be wrapped as ei-

 $ther \verb|convertWarnings(ret <- myfun(args))|, ret <- convertWarnings(myfun(args))|, ret <- convertWarnings($

or more readably ret <- myfun(args) |> convertWarnings())

warning2error a character vector of warning messages that should be converted to errors. Each

warning message is matched using a grep1 expression, so partial matching is supported (though more specific messages are less likely to throw false positives). If NULL then all observed warning messages will be treated as errors

muffle logical; muffle any warning message not caught by warning2error specifica-

tion? Generally not recommended unless you know all of the warning messages

returned by a function

Details

General goal of this function is to *explicitly* indicate warning that are problematic. In many function implementations only a subset of identified warnings should be treated as errors, rather than the more nuclear default of treating all warnings as errors (e.g., see warnings_as_errors in runSimulation, which is primarily included for debugging purposes early in the simulation design, as well as option(warn=2) to convert all warnings to errors globally).

26 convertWarnings

Value

returns the original result of eval(expr)

Author(s)

Phil Chalmers < rphilip.chalmers@gmail.com>

out <- convertWarnings(fun())</pre>
out <- fun() |> convertWarnings()
# errors treated normally
fun(error=TRUE)
fun(error=TRUE) |> convertWarnings()
# all warnings converted to errors
fun(warn1=TRUE)
fun(warn1=TRUE) |> convertWarnings()
fun(warn2=TRUE) |> convertWarnings()
# muffle all non-caught warnings (not recommended unless you know
# the R expression/function very intimately!)
retmuffle <- fun(warn1=TRUE) |>
                 convertWarnings('Warning not caught', muffle=TRUE)
retmuffle
# Specific warnings treated as errors (others stay as warnings)
# Here, treat first warning message as error but not the second or third
fun(warn1=TRUE) # warning
```

createDesign 27

```
ret <- fun(warn1=TRUE) |> convertWarnings("Show this warning") # now error
fun(warn2=TRUE, warn3=TRUE) # warnings
ret23 <- fun(warn2=TRUE, warn3=TRUE) |>
                                          # continues, but prints warnings
             convertWarnings("Show this warning")
ret23
# Explicitly convert multiple warning messages, allowing others through.
   This is generally the best use of the function's specificity
fun(warn1=TRUE, warn2=TRUE)
ret <- fun(warn1=TRUE) |> # error given either message
           convertWarnings(c("Show this warning", "Show a different warning"))
ret <- fun(warn2=TRUE) |>
          convertWarnings(c("Show this warning", "Show a different warning"))
# last warning gets through (left as valid warning), but message still raised
ret3 <- fun(warn3=TRUE) |>
           convertWarnings(c("Show this warning", "Show a different warning"))
ret3
## End(Not run)
```

createDesign

Create the simulation design object

Description

Create a partially or fully-crossed data object reflecting the unique simulation design conditions. Each row of the returned object represents a unique simulation condition, and each column represents the named factor variables under study.

Usage

```
createDesign(
    ...,
    subset,
    fractional = NULL,
    tibble = TRUE,
    stringsAsFactors = FALSE
)

## S3 method for class 'Design'
print(x, list2char = TRUE, pillar.sigfig = 5, ...)
```

28 createDesign

Arguments

... comma separated list of named input objects representing the simulation factors

to completely cross. Note that these arguments are passed to expand.grid to

perform the complete crossings

subset (optional) a logical vector indicating elements or rows to keep to create a par-

tially crossed simulation design

fractional a fractional design matrix returned from the FrF2 package. Note that the order

of the factor names/labels are associated with the respective . . . inputs

tibble logical; return a tibble object instead of a data. frame? Default is TRUE

stringsAsFactors

logical; should character variable inputs be coerced to factors when building a

data.frame? Default is FALSE

x object returned by createDesign

list2char logical; for tibble object re-evaluate list elements as character vectors for better

printing of the levels? Note that this does not change the original classes of the

object, just how they are printed. Default is TRUE

pillar.sigfig number of significant digits to print. Default is 5

Value

a tibble or data. frame containing the simulation experiment conditions to be evaluated in runSimulation

## End(Not run)
```

30 ECR

Description

Computes the detection rate for determining empirical coverage rates given a set of estimated confidence intervals. Note that using 1 - ECR(CIs, parameter) will provide the empirical detection rate. Also supports computing the average width of the CIs, which may be useful when comparing the efficiency of CI estimators.

Usage

```
ECR(
   CIs,
   parameter,
   tails = FALSE,
   CI_width = FALSE,
   complement = FALSE,
   names = NULL,
   unname = FALSE
)
```

Arguments

CIs	a numeric vector of	matrix of con	nfidence interval	values for a	given parame-
-----	---------------------	---------------	-------------------	--------------	---------------

ter value, where the first element/column indicates the lower confidence interval and the second element/column the upper confidence interval. If a vector of length 2 is passed instead then the returned value will be either a 1 or 0 to indicate whether the parameter value was or was not within the interval, respectively.

Otherwise, the input must be a matrix with an even number of columns

parameter a numeric scalar indicating the fixed parameter value. Alternative, a numeric

vector object with length equal to the number of rows as CIs (use to compare

sets of parameters at once)

tails logical; when TRUE returns a vector of length 2 to indicate the proportion of

times the parameter was lower or higher than the supplied interval, respectively. This is mainly only useful when the coverage region is not expected to be symmetric, and therefore is generally not required. Note that 1 - sum(ECR(CIs,

parameter, tails=TRUE)) == ECR(CIs, parameter)

CI_width logical; rather than returning the overall coverage rate, return the average width

of the CIs instead? Useful when comparing the efficiency of different CI esti-

mators

complement logical; rather than computing the proportion of population parameters within

the CI, return the proportion outside the advertised CI (1 - ECR = alpha). In the case where only one value is provided, which normally would return a 0 if outside the CI or 1 if inside, the values will be switched (useful when using, for

example, CI tests of for the significance of parameters)

names an optional character vector used to name the returned object. Generally useful

when more than one CI estimate is investigated at once

unname logical; apply unname to the results to remove any variable names?

EDR

Compute the empirical detection/rejection rate for Type I errors and Power

Description

Computes the detection/rejection rate for determining empirical Type I error and power rates using information from p-values.

Usage

```
EDR(p, alpha = 0.05, unname = FALSE)
```

Arguments

p	a numeric vector or matrix/data.frame of p-values from the desired statistical estimator. If a matrix, each statistic must be organized by column, where the number of rows is equal to the number of replications
alpha	the detection threshold (typical values are .10, .05, and .01). Default is .05
unname	logical; apply unname to the results to remove any variable names?

expandDesign

Create the simulation design object

Description

Repeat each design row the specified number of times. This is primarily used for cluster computing where jobs are distributed with batches of replications and later aggregated into a complete simulation object (see runArraySimulation and aggregate_simulations).

Usage

```
expandDesign(Design, repeat_conditions)
```

Arguments

Design

object created by createDesign which should have its rows repeated for optimal HPC schedulers

repeat_conditions

integer vector used to repeat each design row the specified number of times. Can either be a single integer, which repeats each row this many times, or an integer vector equal to the number of total rows in the created object.

This argument is useful when distributing independent row conditions to cluster computing environments, particularly with different replication information. For example, if 1000 replications in total are the target but the condition is repeated over 4 rows then only 250 replications per row would be required across the repeated conditions. See aggregate_simulations for combining the simulation objects once complete

Value

a tibble or data. frame containing the simulation experiment conditions to be evaluated in runSimulation

34 Generate

Author(s)

Phil Chalmers < rphilip.chalmers@gmail.com>

References

Chalmers, R. P., & Adkins, M. C. (2020). Writing Effective and Reliable Monte Carlo Simulations with the SimDesign Package. The Quantitative Methods for Psychology, 16(4), 248-280. doi:10.20982/tqmp.16.4.p248

See Also

createDesign, aggregate_simulations, runArraySimulation

Examples

Generate

Generate data

Description

Generate data from a single row in the design input (see runSimulation). R contains numerous approaches to generate data, some of which are contained in the base package, as well as in SimDesign (e.g., rmgh, rValeMaurelli, rHeadrick). However the majority can be found in external packages. See CRAN's list of possible distributions here: https://CRAN.R-project.org/view=Distributions. Note that this function technically can be omitted if the data generation is provided in the Analyse step, though in general this is not recommended.

Generate 35

Usage

```
Generate(condition, fixed_objects = NULL)
```

Arguments

condition a single row from the design input (as a data.frame), indicating the simulation

conditions

fixed_objects object passed down from runSimulation

Details

The use of try functions is generally not required in this function because Generate is internally wrapped in a try call. Therefore, if a function stops early then this will cause the function to halt internally, the message which triggered the stop will be recorded, and Generate will be called again to obtain a different dataset. That said, it may be useful for users to throw their own stop commands if the data should be re-drawn for other reasons (e.g., an estimated model terminated correctly but the maximum number of iterations were reached).

Value

returns a single object containing the data to be analyzed (usually a vector, matrix, or data.frame), or list

References

Chalmers, R. P., & Adkins, M. C. (2020). Writing Effective and Reliable Monte Carlo Simulations with the SimDesign Package. The Quantitative Methods for Psychology, 16(4), 248-280. doi:10.20982/tqmp.16.4.p248

36 GenerateIf

```
list(dat=dat, parameters=pars)
}
# similar to above, but using the Attach() function instead of indexing
generate <- function(condition, fixed_objects = NULL) {</pre>
    Attach(condition)
    N1 <- sample_sizes_group1
    N2 <- sample_sizes_group2
    sd <- standard_deviations</pre>
    group1 <- rnorm(N1)</pre>
    group2 <- rnorm(N2, sd=sd)</pre>
    dat <- data.frame(group = c(rep('g1', N1), rep('g2', N2)),</pre>
                       DV = c(group1, group2))
    dat
}
generate2 <- function(condition, fixed_objects = NULL) {</pre>
    mu <- sample(c(-1,0,1), 1)
    dat <- rnorm(100, mu)</pre>
    dat
                #return simple vector (discard mu information)
}
generate3 <- function(condition, fixed_objects = NULL) {</pre>
    mu <- sample(c(-1,0,1), 1)
    dat <- data.frame(DV = rnorm(100, mu))</pre>
}
## End(Not run)
```

GenerateIf

Perform a test that indicates whether a given Generate() function should be executed

Description

This function is designed to prevent specific generate function executions when the design conditions are not met. Primarily useful when the generate argument to runSimulation was input as a named list object, however should only be applied for some specific design condition (otherwise, the data generation moves to the next function in the list).

Usage

```
GenerateIf(x, condition = NULL)
```

GenerateIf 37

Arguments

X	logical statement to evaluate. If the statement evaluates to TRUE then the remainder of the defined function will be evaluated
condition	(optional) the current design condition. This does not need to be supplied if the expression in x evaluates to valid logical (e.g., use Attach(condition) prior to using AnalyseIf, or use with(condition, AnalyseIf(someLogicalTest)))

  mod$p.value
}
```

38 gen_seeds

gen_seeds

Generate random seeds

Description

Generate seeds to be passed to runSimulation's seed input. Values are sampled from 1 to 2147483647, or are generated using L'Ecuyer-CMRG's (2002) method (returning either a list if arrayID is omitted, or the specific row value from this list if arrayID is included).

Usage

```
gen_seeds(design = 1L, iseed = NULL, arrayID = NULL)
```

Arguments

design	design matrix that requires a unique seed per condition, or a number indicating the number of seeds to generate. Default generates one number
iseed	the initial set.seed number used to generate a sequence of independent seeds according to the L'Ecuyer-CMRG (2002) method. This is recommended whenever quality random number generation is required across similar (if not identical) simulation jobs (e.g., see runArraySimulation). If arrayID is not specified then this will return a list of the associated seed for the full design
arrayID	(optional) single integer input corresponding to the specific row in the design object when using the iseed input. This is used in functions such as runArraySimulation to pull out the specific seed rather than manage a complete list, and is therefore more memory efficient

Author(s)

Phil Chalmers < rphilip.chalmers@gmail.com>

getArrayID 39

Examples

```
# generate 1 seed (default)
gen_seeds()
# generate 5 unique seeds
gen_seeds(5)
# generate from nrow(design)
design <- createDesign(factorA=c(1,2,3),</pre>
                        factorB=letters[1:3])
seeds <- gen_seeds(design)</pre>
seeds
# generate seeds for runArraySimulation()
(iseed <- gen_seeds()) # initial seed
seed_list <- gen_seeds(design, iseed=iseed)</pre>
seed_list
# expand number of unique seeds given iseed (e.g., in case more replications
# are required at a later date)
seed_list_tmp <- gen_seeds(nrow(design)*2, iseed=iseed)</pre>
str(seed_list_tmp) # first 9 seeds identical to seed_list
# more usefully for HPC, extract only the seed associated with an arrayID
arraySeed.15 <- gen_seeds(nrow(design)*2, iseed=iseed, arrayID=15)</pre>
arraySeed.15
```

getArrayID

Get job array ID (e.g., from SLURM or other HPC array distributions)

Description

Get the array ID from an HPC array distribution job (e.g., from SLURM or from optional command line arguments). The array ID is used to index the rows in the design object in runArraySimulation. For instance, a SLURM array with 10 independent jobs might have the following shell instructions.

Usage

```
getArrayID(type = "slurm", trailingOnly = TRUE)
```

Arguments

type an integer indicating the element from the result of commandArgs to extract, or

a character specifying the the type of. Default is 'slurm'

trailingOnly logical value passed to commandArgs. Only used when type is an integer

40 IRMSE

Details

```
#!/bin/bash -1
#SBATCH --time=00:01:00
#SBATCH --array=1-10
```

which names the associated jobs with the numbers 1 through 10. getArrayID() then extracts this information per array, which is used as the runArraySimulation(design, ..., arrayID = getArrayID()) to pass specific rows for the design object.

See Also

```
runArraySimulation
```

Examples

```
## Not run:
# get slurm array ID
arrayID <- getArrayID()
# get ID based on first optional argument in shell specification
arrayID <- getArrayID(type = 1)
# pass to
# runArraySimulation(design, ...., arrayID = arrayID)
## End(Not run)</pre>
```

IRMSE

Compute the integrated root mean-square error

Description

Computes the average/cumulative deviation given two continuous functions and an optional function representing the probability density function. Only one-dimensional integration is supported.

Usage

```
IRMSE(
   estimate,
   parameter,
   fn,
   density = function(theta, ...) 1,
   lower = -Inf,
   upper = Inf,
   ...
)
```

IRMSE 41

Arguments

estimate a vector of parameter estimates
parameter a vector of population parameters

fn a continuous function where the first argument is to be integrated and the sec-

ond argument is a vector of parameters or parameter estimates. This function represents a implied continuous function which uses the sample estimates or

population parameters

density (optional) a density function used to marginalize (i.e., average), where the first

argument is to be integrated, and must be of the form density(theta, ...) or density(theta, param1, param2), where param1 is a placeholder name for the hyper-parameters associated with the probability density function. If omitted then the cumulative different between the respective functions will be computed

instead

lower lower bound to begin numerical integration from upper upper bound to finish numerical integration to

... additional parameters to pass to fnest, fnparam, density, and integrate,

Details

The integrated root mean-square error (IRMSE) is of the form

$$IRMSE(\theta) = \sqrt{\int [f(\theta, \hat{\psi}) - f(\theta, \psi)]^2 g(\theta, ...)}$$

where $g(\theta,...)$ is the density function used to marginalize the continuous sample $(f(\theta,\hat{\psi}))$ and population $(f(\theta,\psi))$ functions.

Value

returns a single numeric term indicating the average/cumulative deviation given the supplied continuous functions

# integrated RMSE result by marginalizing over a N(0,1) distribution
den <- function(theta, mean, sd) dnorm(theta, mean=mean, sd=sd)</pre>
IRMSE(est, pop, fn, den, mean=0, sd=1)
# this specification is equivalent to the above
den2 <- function(theta, ...) dnorm(theta, ...)</pre>
IRMSE(est, pop, fn, den2, mean=0, sd=1)
```

MAE

Compute the mean absolute error

Description

Computes the average absolute deviation of a sample estimate from the parameter value. Accepts estimate and parameter values, as well as estimate values which are in deviation form.

Usage

```
MAE(estimate, parameter = NULL, type = "MAE", percent = FALSE, unname = FALSE)
```

Arguments

estimate

a numeric vector, matrix/data.frame, or list of parameter estimates. If a vector, the length is equal to the number of replications. If a matrix/data.frame the number of rows must equal the number of replications. list objects will be looped over using the same rules after above after first translating the information into one-dimensional vectors and re-creating the structure upon return

MAE 43

parameter a numeric scalar/vector or matrix indicating the fixed parameter values. If a

single value is supplied and estimate is a matrix/data.frame then the value will be recycled for each column; otherwise, each element will be associated with each respective column in the estimate input. If NULL, then it will be assumed that the estimate input is in a deviation form (therefore mean(abs(estimate))

will be returned)

type of deviation to compute. Can be 'MAE' (default) for the mean absolute er-

ror, 'NMSE' for the normalized MAE (MAE / (max(estimate) - min(estimate))),

or 'SMSE' for the standardized MAE (MAE / sd(estimate))

percent logical; change returned result to percentage by multiplying by 100? Default is

FALSE

unname logical; apply unname to the results to remove any variable names?

Value

returns a numeric vector indicating the overall mean absolute error in the estimates

```

MSRSE

Compute the relative performance behavior of collections of standard errors

Description

The mean-square relative standard error (MSRSE) compares standard error estimates to the standard deviation of the respective parameter estimates. Values close to 1 indicate that the behavior of the standard errors closely matched the sampling variability of the parameter estimates.

Usage

```
MSRSE(SE, SD, percent = FALSE, unname = FALSE)
```

Arguments

SE	a numeric scalar/vector indicating the average standard errors across the replications, or a matrix of collected standard error estimates themselves to be used to compute the average standard errors. Each column/element in this input corresponds to the column/element in SD
SD	a numeric scalar/vector indicating the standard deviation across the replications, or a matrix of collected parameter estimates themselves to be used to compute the standard deviations. Each column/element in this input corresponds to the column/element in SE
percent	logical; change returned result to percentage by multiplying by 100? Default is FALSE
unname	logical; apply unname to the results to remove any variable names?

Details

Mean-square relative standard error (MSRSE) is expressed as

$$MSRSE = \frac{E(SE(\psi)^{2})}{SD(\psi)^{2}} = \frac{1/R * \sum_{r=1}^{R} SE(\psi_{r})^{2}}{SD(\psi)^{2}}$$

where $SE(\psi_r)$ represents the estimate of the standard error at the rth simulation replication, and $SD(\psi)$ represents the standard deviation estimate of the parameters across all R replications. Note that $SD(\psi)^2$ is used, which corresponds to the variance of ψ .

MSRSE 45

Value

returns a vector of ratios indicating the relative performance of the standard error estimates to the observed parameter standard deviation. Values less than 1 indicate that the standard errors were larger than the standard deviation of the parameters (hence, the SEs are interpreted as more conservative), while values greater than 1 were smaller than the standard deviation of the parameters (i.e., more liberal SEs)

results
```

46 nc

Auto-named Concatenation of Vector or List

nc

Description

This is a wrapper to the function c, however names the respective elements according to their input object name. For this reason, nesting nc() calls is not recommended (joining independent nc() calls via c() is however reasonable).

Usage

```
nc(..., use.names = FALSE, error.on.duplicate = TRUE)
```

Arguments

```
... objects to be concatenated
use.names logical indicating if names should be preserved (unlike c, default is FALSE)
error.on.duplicate
```

logical; if the same object name appears in the returning object should an error be thrown? Default is TRUE

```

48 PBA

PBA

Probabilistic Bisection Algorithm

Description

The function PBA searches a specified interval for a root (i.e., zero) of the function f(x) with respect to its first argument. However, this function differs from deterministic cousins such as uniroot in that f may contain stochastic error components, and instead provides a Bayesian interval where the root is likely to lie. Note that it is assumed that E[f(x)] is non-decreasing in x and that the root is between the search interval (evaluated approximately when check interval=TRUE). See Waeber, Frazier, and Henderson (2013) for details.

Usage

```
PBA(
  f,
  interval,
  p = 0.6,
  integer = FALSE,
  tol = if (integer) 0.01 else 1e-04,
  maxiter = 300L,
 miniter = 100L,
 wait.time = NULL,
  f.prior = NULL,
  resolution = 10000L,
  check.interval = TRUE,
  check.interval.only = FALSE,
  verbose = TRUE
)
## S3 method for class 'PBA'
print(x, ...)
## S3 method for class 'PBA'
plot(x, type = "posterior", main = "Probabilistic Bisection Posterior", ...)
```

Arguments

f	noisy function for which the root is sought
interval	a vector containing the end-points of the interval to be searched for the root
	additional named arguments to be passed to f
p	assumed constant for probability of correct responses (must be > 0.5)
integer	logical; should the values of the root be considered integer or numeric? The former uses a discreet grid to track the updates, while the latter currently creates a grid with resolution points

PBA 49

tol	tolerance criteria for convergence based on average of the f(x) evaluations	

maxiter the maximum number of iterations (default 300) miniter minimum number of iterations (default 100)

wait.time (optional) instead of terminating after specific estimate criteria are satisfied (e.g.,

tol), terminate after a specific wait time. Input must be a numeric vector indicating the number of minutes to wait. Not that users should increase the number of maxiter as well so that termination can occur if either the maximum iterations are satisfied or the specified wait time has elapsed (whichever occurs first)

f.prior density function indicating the likely location of the prior (e.g., if root is within

[0,1] then dunif works, otherwise custom functions will be required)

resolution constant indicating the number of equally spaced grid points to track when

integer = FALSE.

check.interval logical; should an initial check be made to determine whether f(interval[1L])

and f(interval[2L]) have opposite signs? Default is TRUE

check.interval.only

logical; return only TRUE or FALSE to test whether there is a likely root given interval? Setting this to TRUE can be useful when you are unsure about the root location interval and may want to use a higher replication input from

SimSolve

verbose logical; should the iterations and estimate be printed to the console?

x an object of class PBA

type type of plot to draw for PBA object. Can be either 'posterior' or 'history' to plot

the PBA posterior distribution or the mediation iteration history

main plot title

quiet

Suppress function messages and Concatenate and Print (cat)

Description

This function is used to suppress information printed from external functions that make internal use of link{message} and cat, which provide information in interactive R sessions. For simulations, the session is not interactive, and therefore this type of output should be suppressed. For similar behaviour for suppressing warning messages see suppressWarnings, though use this function carefully as some warnings can be meaningful and unexpected.

RAB 51

Usage

```
quiet(..., messages = FALSE, cat = FALSE)
```

Arguments

... the functional expression to be evaluated

messages logical; suppress all messages?

cat logical; suppress all concatenate and print calls from cat?

RAB

Compute the relative absolute bias of multiple estimators

Description

Computes the relative absolute bias given the bias estimates for multiple estimators.

Usage

```
RAB(x, percent = FALSE, unname = FALSE)
```

52 rbind.SimDesign

Arguments

used as the reference

percent logical; change returned result to percentage by multiplying by 100? Default is

FALSE

unname logical; apply unname to the results to remove any variable names?

Value

returns a vector of absolute bias ratios indicating the relative bias effects compared to the first estimator. Values less than 1 indicate better bias estimates than the first estimator, while values greater than 1 indicate worse bias than the first estimator

rbind.SimDesign

Combine two separate SimDesign objects by row

Description

This function combines two Monte Carlo simulations executed by SimDesign's runSimulation function which, for all intents and purposes, could have been executed in a single run. This situation arises when a simulation has been completed, however the Design object was later modified to include more levels in the defined simulation factors. Rather than re-executing the previously completed simulation combinations, only the new combinations need to be evaluated into a different object and then rbind together to create the complete object combinations.

rbind.SimDesign 53

Usage

```
## S3 method for class 'SimDesign'
rbind(...)
```

Arguments

... two or more SimDesign objects that should be combined by rows

Value

same object that is returned by runSimulation

Author(s)

Phil Chalmers < rphilip.chalmers@gmail.com>

RD

Compute the relative difference

Description

Computes the relative difference statistic of the form (est - pop)/ pop, which is equivalent to the form est/pop - 1. If matrices are supplied then an equivalent matrix variant will be used of the form (est - pop) * solve(pop). Values closer to 0 indicate better relative parameter recovery. Note that for single variable inputs this is equivalent to bias(..., type = 'relative').

Usage

```
RD(est, pop, as.vector = TRUE, unname = FALSE)
```

Arguments

est	a numeric vector, matrix/data.frame, or list containing the parameter estimates
pop	a numeric vector or matrix containing the true parameter values. Must be of comparable dimension to est
as.vector	logical; always wrap the result in a as.vector function before returning?
unname	logical; apply unname to the results to remove any variable names?

RE 55

Value

returns a vector or matrix depending on the inputs and whether as. vector was used

Author(s)

Phil Chalmers < rphilip.chalmers@gmail.com>

References

Examples

```
# vector
pop <- seq(1, 100, length.out=9)
est1 <- pop + rnorm(9, 0, .2)
(rds <- RD(est1, pop))
summary(rds)

# matrix
pop <- matrix(c(1:8, 10), 3, 3)
est2 <- pop + rnorm(9, 0, .2)
RD(est2, pop, as.vector = FALSE)
(rds <- RD(est2, pop))
summary(rds)</pre>
```

RE

Compute the relative efficiency of multiple estimators

Description

Computes the relative efficiency given the RMSE (default) or MSE values for multiple estimators.

Usage

```
RE(x, MSE = FALSE, percent = FALSE, unname = FALSE)
```

56 RE

Arguments

х	a numeric vector of root mean square error values (see RMSE), where the first element will be used as the reference. Otherwise, the object could contain MSE values if the flag MSE = TRUE is also included
MSE	logical; are the input value mean squared errors instead of root mean square errors?
percent	logical; change returned result to percentage by multiplying by 100? Default is FALSE
unname	logical; apply unname to the results to remove any variable names?

Value

returns a vector of variance ratios indicating the relative efficiency compared to the first estimator. Values less than 1 indicate better efficiency than the first estimator, while values greater than 1 indicate worse efficiency than the first estimator

rejectionSampling 57

rejectionSampling

Rejection sampling (i.e., accept-reject method)

Description

This function supports the rejection sampling (i.e., accept-reject) approach to drawing values from seemingly difficult (probability) density functions by sampling values from more manageable proxy distributions.

Usage

```
rejectionSampling(
    n,
    df,
    dg,
    rg,
    M,
    method = "optimize",
    interval = NULL,
    logfuns = FALSE,
    maxM = 1e+05,
    parstart = rg(1L),
    ESRS_Mstart = 1.0001
)
```

Arguments

df

dg

n number of samples to draw

the desired (potentially un-normed) density function to draw independent samples from. Must be in the form of a function with a single input corresponding to the values sampled from rg. Function is assumed to be vectorized (if not, see Vectorize)

the proxy (potentially un-normed) density function to draw samples from in lieu of drawing samples from df. The support for this density function should be the same as df (i.e., when df(x) > 0 then dg(x) > 0). Must be in the form of a function with a single input corresponding to the values sampled from rg. Function is assumed to be vectorized (if not, see Vectorize)

the proxy random number generation function, associated with dg, used to draw proposal samples from. Must be in the form of a function with a single input corresponding to the number of values to draw, while the output can either be a vector or a matrix (if a matrix, each independent observation must be stored in a unique row). Function is assumed to be vectorized (if not, see Vectorize)

the upper-bound of the ratio of probability density functions to help minimize the number of discarded draws and define the corresponding rescaled proposal envelope. When missing, M is computed internally by finding a reasonable maximum of log(df(x)) - log(dg(x)), and this value is returned to the console.

rg

М

58 rejectionSampling

When both df and dg are true probability density functions (i.e., integrate to 1)

the acceptance probability is equal to 1/M

method when M is missing, the optimization of M is done either by finding the mode

of the log-density values ("optimize") or by using the "Empirical Supremum

Rejection Sampling" method ("ESRS")

interval when M is missing, for univariate density function draws, the interval to search

within via optimize. If not specified, a sample of 5000 values from the rg function definition will be collected, and the min/max will be obtained via this

random sample

logical; have the df and dg function been written so as to return log-densities

instead of the original densities? The FALSE default assumes the original densities are returned (use TRUE when higher accuracy is required when generating

each density definition)

maxM logical; if when optimizing M the value is greater than this cut-off then stop;

ampler would likelihood be too efficient, or optimization is failing

parstart starting value vector for optimization of M in multidimensional distributions

ESRS_Mstart starting M value for the ESRS algorithm

Details

The accept-reject algorithm is a flexible approach to obtaining i.i.d.'s from a difficult to sample from (probability) density function where either the transformation method fails or inverse transform method is difficult to manage. The algorithm does so by sampling from a more "well-behaved" proxy distribution (with identical support, up to some proportionality constant M that reshapes the proposal density to envelope the target density), and accepts the draws if they are likely within the target density. Hence, the closer the shape of dg(x) is to the desired df(x), the more likely the draws are to be accepted; otherwise, many iterations of the accept-reject algorithm may be required, which decreases the computational efficiency.

Value

returns a vector or matrix of draws (corresponding to the output class from rg) from the desired df

reSummarise

Run a summarise step for results that have been saved to the hard drive

Description

When runSimulation() uses the option save_results = TRUE the R replication results from the Generate-Analyse functions are stored to the hard drive. As such, additional summarise components may be required at a later time, whereby the respective .rds files must be read back into R to be summarised. This function performs the reading of these files, application of a provided summarise function, and final collection of the respective results.

Usage

```
reSummarise(
  summarise,
  dir = NULL,
  files = NULL,
  results = NULL,
  Design = NULL,
  fixed_objects = NULL,
```

reSummarise 61

```
boot_method = "none",
boot_draws = 1000L,
CI = 0.95,
prefix = "results-row"
```

Arguments

summarise

a summarise function to apply to the read-in files. See runSimulation for details

dir directory pointing to the .rds files to be read-in that were saved from runSimulation(...,

save_results=TRUE). If NULL, it is assumed the current working directory con-

tains the .rds files

files (optional) names of files to read-in. If NULL all files located within dir will be

used

results (optional) the results of runSimulation when no summarise function was pro-

> vided. Can be either a tibble or matrix (indicating that exactly one design condition was evaluated), or a list of matrix/tibble objects indicating that

multiple conditions were performed with no summarise evaluation.

Alternatively, if store_results = TRUE in the runSimulation() execution then the final SimDesign object may be passed, where the generate-analyse informa-

tion will be extracted from the object instead

Design (optional) if results input used, and design condition information important

in the summarise step, then the original design object from runSimulation

should be included

fixed_objects (optional) see runSimulation for details

method for performing non-parametric bootstrap confidence intervals for the reboot_method

spective meta-statistics computed by the Summarise function. See runSimulation

for details

boot_draws number of non-parametric bootstrap draws to sample for the summarise func-

tion after the generate-analyse replications are collected. Default is 1000

CI bootstrap confidence interval level (default is 95%) prefix character indicating prefix used for stored files

rHeadrick 63

					•	
r	н	ea	אנ	r.	1 ^	v

Generate non-normal data with Headrick's (2002) method

Description

Generate multivariate non-normal distributions using the fifth-order polynomial method described by Headrick (2002).

Usage

```
rHeadrick(
    n,
    mean = rep(0, nrow(sigma)),
    sigma = diag(length(mean)),
    skew = rep(0, nrow(sigma)),
    kurt = rep(0, nrow(sigma)),
    gam3 = NaN,
    gam4 = NaN,
    return_coefs = FALSE,
    coefs = NULL,
    control = list(trace = FALSE, max.ntry = 15, obj.tol = 1e-10, n.valid.sol = 1)
)
```

Arguments

n	number of samples to draw
mean	a vector of k elements for the mean of the variables
sigma	desired k x k covariance matrix between bivariate non-normal variables
skew	a vector of k elements for the skewness of the variables
kurt	a vector of k elements for the kurtosis of the variables
gam3	(optional) explicitly supply the gamma 3 value? Default computes this internally
gam4	(optional) explicitly supply the gamma 4 value? Default computes this internally
return_coefs	logical; return the estimated coefficients only? See below regarding why this is useful.
coefs	(optional) supply previously estimated coefficients? This is useful when there must be multiple data sets drawn and will avoid repetitive computations. Must be the object returned after passing return_coefs = TRUE
control	a list of control parameters when locating the polynomial coefficients

Details

This function is primarily a wrapper for the code written by Oscar L. Olvera Astivia (last edited Feb 26, 2015) with some modifications (e.g., better starting values for the Newton optimizer, passing previously saved coefs, etc).

## End(Not run)
```

rint 65

rint

Generate integer values within specified range

Description

Efficiently generate positive and negative integer values with (default) or without replacement. This function is mainly a wrapper to the sample.int function (which itself is much more efficient integer sampler than the more general sample), however is intended to work with both positive and negative integer ranges since sample.int only returns positive integer values that must begin at 1L.

Usage

```
rint(n, min, max, replace = TRUE, prob = NULL)
```

Arguments

n number of samples to draw

min lower limit of the distribution. Must be finite max upper limit of the distribution. Must be finite

replace should sampling be with replacement?

prob a vector of probability weights for obtaining the elements of the vector being

sampled

x <- rint(1000, min = -20, max = 20)
summary(x)</pre>
```

rinvWishart

Generate data with the inverse Wishart distribution

Description

Function generates data in the form of symmetric matrices from the inverse Wishart distribution given a covariance matrix and degrees of freedom.

Usage

```
rinvWishart(n = 1, df, sigma)
```

Arguments

n number of matrix observations to generate. By default n = 1, which returns a single symmetric matrix. If n > 1 then a list of n symmetric matrices are returned instead

df degrees of freedom

sigma positive definite covariance matrix

Value

a numeric matrix with columns equal to ncol(sigma) when n = 1, or a list of n matrices with the same properties

x</pre>
```

rmgh

Generate data with the multivariate g-and-h distribution

Description

Generate non-normal distributions using the multivariate g-and-h distribution. Can be used to generate several different classes of univariate and multivariate distributions.

Usage

```
rmgh(n, g, h, mean = rep(0, length(g)), sigma = diag(length(mean)))
```

Arguments

n	number of samples to draw
g	the g parameter(s) which control the skew of a distribution in terms of both direction and magnitude
h	the h parameter(s) which control the tail weight or elongation of a distribution and is positively related with kurtosis
mean	a vector of k elements for the mean of the variables
sigma	desired k x k covariance matrix between bivariate non-normal variables

68 RMSE

Examples

```
set.seed(1)
# univariate
norm <- rmgh(10000,1e-5,0)
hist(norm)
skew <- rmgh(10000, 1/2, 0)
hist(skew)
neg_skew_platykurtic <- rmgh(10000,-1,-1/2)</pre>
hist(neg_skew_platykurtic)
# multivariate
sigma <- matrix(c(2,1,1,4), 2)
mean <- c(-1, 1)
twovar <- rmgh(10000, c(-1/2, 1/2), c(0,0),
    mean=mean, sigma=sigma)
hist(twovar[,1])
hist(twovar[,2])
plot(twovar)
```

RMSE

Compute the (normalized) root mean square error

Description

Computes the average deviation (root mean square error; also known as the root mean square deviation) of a sample estimate from the parameter value. Accepts estimate and parameter values, as well as estimate values which are in deviation form.

Usage

```
RMSE(
    estimate,
    parameter = NULL,
    type = "RMSE",
    MSE = FALSE,
    percent = FALSE,
    unname = FALSE
)

RMSD(
    estimate,
    parameter = NULL,
    type = "RMSE",
```

RMSE 69

```
MSE = FALSE,
percent = FALSE,
unname = FALSE
)
```

Arguments

estimate a numeric vector, matrix/data.frame, or list of parameter estimates. If a

vector, the length is equal to the number of replications. If a matrix/data.frame, the number of rows must equal the number of replications. list objects will be looped over using the same rules after above after first translating the information into one-dimensional vectors and re-creating the structure upon return

parameter a numeric scalar/vector indicating the fixed parameter values. If a single value

is supplied and estimate is a matrix/data.frame then the value will be recycled for each column; otherwise, each element will be associated with each respective column in the estimate input. If NULL then it will be assumed that the estimate input is in a deviation form (therefore sqrt(mean(estimate^2))

will be returned)

type type of deviation to compute. Can be 'RMSE' (default) for the root mean square-

error, 'NRMSE' for the normalized RMSE (RMSE / (max(estimate) - min(estimate))), 'SRMSE' for the standardized RMSE (RMSE / sd(estimate)), 'CV' for the coef-

ficient of variation, or 'RMSLE' for the root mean-square log-error

MSE logical; return the mean square error equivalent of the results instead of the root

mean-square error (in other words, the result is squared)? Default is FALSE

percent logical; change returned result to percentage by multiplying by 100? Default is

FALSE

unname logical; apply unname to the results to remove any variable names?

Value

returns a numeric vector indicating the overall average deviation in the estimates

rmvt

Generate data with the multivariate t distribution

Description

Function generates data from the multivariate t distribution given a covariance matrix, non-centrality parameter (or mode), and degrees of freedom.

72 rmvt

Usage

```
rmvt(n, sigma, df, delta = rep(0, nrow(sigma)), Kshirsagar = FALSE)
```

Arguments

n	number of observations to generate
sigma	positive definite covariance matrix
df	degrees of freedom. df = 0 and df = Inf corresponds to the multivariate normal distribution
delta	the vector of non-centrality parameters of length n which specifies the either the modes (default) or non-centrality parameters
Kshirsagar	logical; triggers whether to generate data with non-centrality parameters or to

adjust the simulated data to the mode of the distribution. The default uses the

mode

Value

a numeric matrix with columns equal to ncol(sigma)

RobbinsMonro 73

RobbinsMonro

Robbins-Monro (1951) stochastic root-finding algorithm

Description

Function performs stochastic root solving for the provided f(x) using the Robbins-Monro (1951) algorithm. Differs from deterministic cousins such as uniroot in that f may contain stochastic error components, where the root is obtained through the running average method provided by noise filter (see also PBA). Assumes that E[f(x)] is non-decreasing in x.

Usage

```
RobbinsMonro(
  f,
 р,
  . . . ,
 Polyak_Juditsky = FALSE,
 maxiter = 500L,
 miniter = 100L,
  k = 3L
  tol = 1e-05,
  verbose = TRUE,
  fn.a = function(iter, a = 1, b = 1/2, c = 0, ...) a/(iter + c)^b
)
## S3 method for class 'RM'
print(x, ...)
## S3 method for class 'RM'
plot(x, par = 1, main = NULL, Polyak_Juditsky = FALSE, ...)
```

Arguments

f noisy function for which the root is sought
p vector of starting values to be passed as f(p, ...)
... additional named arguments to be passed to f
Polyak_Juditsky

logical; apply the Polyak and Juditsky (1992) running-average method? Returns the final running average estimate using the Robbins-Monro updates (also applies to plot). Note that this should only be used when the step-sizes are sufficiently large so that the Robbins-Monro have the ability to stochastically explore around the root (not just approach it from one side, which occurs when using small steps)

maxiter the maximum number of iterations (default 500) miniter minimum number of iterations (default 100)

74 RobbinsMonro

k	number of consecutive tol criteria required before terminating
tol	tolerance criteria for convergence on the changes in the updated p elements. Must be achieved on k (default 3) successive occasions
verbose	logical; should the iterations and estimate be printed to the console?
fn.a	function to create the a coefficient in the Robbins-Monro noise filter. Requires the first argument is the current iteration (iter), provide one or more arguments, and (optionally) the \dots Sequence function is of the form recommended by Spall (2000).
	Note that if a different function is provided it must satisfy the property that $\sum_{i=1}^\infty a_i=\infty$ and $\sum_{i=1}^\infty a_i^2<\infty$
x	an object of class RM
par	which parameter in the original vector p to include in the plot
main	plot title

plot(retrm.PJ, Polyak_Juditsky = TRUE) # Polyak_Juditsky history
```

RSE

Compute the relative standard error ratio

Description

Computes the relative standard error ratio given the set of estimated standard errors (SE) and the deviation across the R simulation replications (SD). The ratio is formed by finding the expectation of the SE terms, and compares this expectation to the general variability of their respective parameter estimates across the R replications (ratio should equal 1). This is used to roughly evaluate whether the SEs being advertised by a given estimation method matches the sampling variability of the respective estimates across samples.

Usage

```
RSE(SE, ests, unname = FALSE)
```

Arguments

SE

a numeric matrix of SE estimates across the replications (extracted from the results object in the Summarise step). Alternatively, can be a vector containing the mean of the SE estimates across the R simulation replications

76 rtruncate

ests a numeric matrix object containing the parameter estimates under investigation

found within the Summarise function. This input is used to compute the standard deviation/variance estimates for each column to evaluate how well the expected

SE matches the standard deviation

unname logical; apply unname to the results to remove any variable names?

Value

returns vector of variance ratios, $(RSV = SE^2/SD^2)$

Examples

rtruncate

Generate a random set of values within a truncated range

Description

Function generates data given a supplied random number generating function that are constructed to fall within a particular range. Sampled values outside this range are discarded and re-sampled until the desired criteria has been met.

rtruncate 77

Usage

```
rtruncate(n, rfun, range, ..., redraws = 100L)
```

Arguments

n number of observations to generate. This should be the first argument passed to

rfun

rfun a function to generate random values. Function can return a numeric/integer

vector or matrix, and additional arguments requred for this function are passed

through the argument . . .

range a numeric vector of length two, where the first element indicates the lower bound

and the second the upper bound. When values are generated outside these two bounds then data are redrawn until the bounded criteria is met. When the output of rfun is a matrix then this input can be specified as a matrix with two rows, where each the first row corresponds to the lower bound and the second row the

upper bound for each generated column in the output

... additional arguments to be passed to rfun

redraws the maximum number of redraws to take before terminating the iterative se-

quence. This is in place as a safety in case the range is too small given the random number generator, causing too many consecutive rejections. Default is

100

Details

In simulations it is often useful to draw numbers from truncated distributions rather than across the full theoretical range. For instance, sampling parameters within the range [-4,4] from a normal distribution. The rtruncate function has been designed to accept any sampling function, where the first argument is the number of values to sample, and will draw values iteratively until the number of values within the specified bound are obtained. In situations where it is unlikely for the bounds to be located (e.g., sampling from a standard normal distribution where all values are within [-10,-6]) then the sampling scheme will throw an error if too many re-sampling executions are required (default will stop if more that 100 calls to rfun are required).

Value

either a numeric vector or matrix, where all values are within the desired range

runArraySimulation

Run a Monte Carlo simulation using array job submissions per condition

Description

This function has the same purpose as runSimulation, however rather than evaluating each row in a design object (potentially with parallel computing architecture) this function evaluates the simulation per independent row condition. This is mainly useful when distributing the jobs to HPC clusters where a job array number is available (e.g., via SLURM), where the simulation results must be saved to independent files as they complete. Use of expandDesign is useful for distributing replications to different jobs, while gen_seeds is required to ensure high-quality random number generation across the array submissions. See the associated vignette for a brief tutorial of this setup.

Usage

```
runArraySimulation(
  design,
    ...,
  replications,
  iseed,
  filename,
```

```
dirname = NULL,
  arrayID = getArrayID(),
  filename_suffix = paste0("-", arrayID),
  addArrayInfo = TRUE,
  save_details = list(),
  control = list()
```

Arguments

design object containing simulation conditions on a per row basis. This func-

tion is design to submit each row as in independent job on a HPC cluster. See

runSimulation for further details

... additional arguments to be passed to runSimulation

replications number of independent replications to perform per condition (i.e., each row in

design). See runSimulation for further details

iseed initial seed to be passed to gen_seeds's argument of the same name, along with

the supplied arrayID

file name to save simulation files to (does not need to specify extension). How-

ever, the array ID will be appended to each filename (see filename_suffix). For example, if filename = 'mysim' then files stored will be 'mysim-1.rds',

'mysim-2.rds', and so on for each row in design

dirname directory to save the files associated with filename to. If omitted the files will

be stored in the same working directory where the script was submitted

arrayID array identifier from the scheduler. Must be a number between 1 and nrow(design).

If not specified then getArrayID will be called automatically, which assumes the environmental variables are available according the SLURM scheduler

filename_suffix

suffix to add to the filename; default add '-' with the arrayID

addArrayInfo logical; should the array ID and original design row number be added to the

SimExtract(..., what='results') output?

save_details optional list of extra file saving details. See runSimulation

control control list passed to runSimulation. In addition to the original control elements two additional arguments have been added: max_time and max_RAM, both

of which as specified as character vectors with one element.

max_time specifies the maximum time allowed for a single simulation condition to execute (default does not set any time limits). This is primarily useful when the HPC cluster will time out after some known elapsed time. Following the SBATCH specifications, acceptable time formats include "minutes",

"minutes:seconds", "hours:minutes:seconds", "days-hours", "days-hours:minutes"

and "days-hours:minutes:seconds". For example, max_time = "60" indicates a maximum time of 60 minutes, max_time = "03:00:00" a maximum time of 3 hours, max_time = "4-12" a maximum of 4 days and 12 hours, and max_time = "2-02:30:00" a maximum of 2 days, 2 hours and 30 minutes. In general, this input should be set to somewhere around 80-90 before the cluster

is terminated can be saved. Default applies no time limit

Similarly, max_RAM controls the (approximate) maximum size that the simulation storage objects can grow before RAM becomes an issue. This can be specified either in terms of megabytes (MB), gigabytes (GB), or terabytes (TB). For example, max_RAM = "4GB" indicates that if the simulation storage objects are larger than 4GB then the workflow will terminate early, returning only the successful results up to this point). Useful for larger HPC cluster jobs with RAM constraints that could terminate abruptly. As a rule of thumb this should be set to around 90 available. Default applies no memory limit

Details

Due to the nature of how the replication are split it is important that the L'Ecuyer-CMRG (2002) method of random seeds is used across all array ID submissions (cf. runSimulation's parallel approach, which uses this method to distribute random seeds within each isolated condition rather than between all conditions). As such, this function requires the seeds to be generated using gen_seeds with the iseed and arrayID inputs to ensure that each job is analyzing a high-quality set of random numbers via L'Ecuyer-CMRG's (2002) method.

Additionally, for timed simulations on HPC clusters it is also recommended to pass a control = list(max_time) value to avoid discarding conditions that require more than the specified time in the shell script. The max_time value should be less than the maximum time allocated on the HPC cluster (e.g., approximately 90 depends on how long each replication takes). Simulations with missing replication information should submit a new set of jobs at a later time to collect the missing replication information.

runSimulation

Run a Monte Carlo simulation given conditions and simulation functions

Description

This function runs a Monte Carlo simulation study given a set of predefined simulation functions, design conditions, and number of replications. Results can be saved as temporary files in case of interruptions and may be restored by re-running runSimulation, provided that the respective temp file can be found in the working directory. runSimulation supports parallel and cluster computing (with the parallel and future packages; see also runArraySimulation for submitting array jobs to HPC clusters), global and local debugging, error handling (including fail-safe stopping when functions fail too often, even across nodes), provides bootstrap estimates of the sampling variability (optional), and automatic tracking of error and warning messages with their associated .Random.seed states. For convenience, all functions available in the R work-space are exported across all nodes so that they are more easily accessible (however, other R objects are not, and therefore must be passed to the fixed_objects input to become available across nodes).

Usage

```
runSimulation(
  design,
  replications,
  generate,
  analyse,
  summarise,
  fixed_objects = NULL,
  packages = NULL,
  filename = NULL,
  debug = "none",
  load_seed = NULL,
  save = any(replications > 2),
  store_results = TRUE,
  save_results = FALSE,
  parallel = FALSE,
  ncores = parallel::detectCores() - 1L,
  c1 = NULL,
  notification = "none",
  beep = FALSE,
  sound = 1,
 CI = 0.95,
  seed = NULL,
  boot_method = "none",
  boot_draws = 1000L,
 max_errors = 50L,
  resume = TRUE,
  save_details = list(),
  control = list(),
  progress = TRUE,
  verbose = TRUE
)
## S3 method for class 'SimDesign'
```

```
summary(object, ...)
## S3 method for class 'SimDesign'
print(x, list2char = TRUE, ...)
```

Arguments

design

a tibble or data.frame object containing the Monte Carlo simulation conditions to be studied, where each row represents a unique condition and each column a factor to be varied. See createDesign for the standard approach to create this simulation design object

replications

number of independent replications to perform per condition (i.e., each row in design). Can be a single number, which will be used for each design condition, or an integer vector with length equal to nrow(design). All inputs must be greater than 0

generate

user-defined data and parameter generating function (or named list of functions). See Generate for details. Note that this argument may be omitted by the user if they wish to generate the data with the analyse step, but for real-world simulations this is generally not recommended. If multiple generate functions are provided as a list then the list of generate functions are executed in order until the first valid generate function is executed, where the subsequent generation functions are then ignored (see GenerateIf to only apply data generation for specific conditions).

analyse

user-defined analysis function (or named list of functions) that acts on the data generated from Generate (or, if generate was omitted, can be used to generate and analyses the simulated data). See Analyse for details

summarise

optional (but strongly recommended) user-defined summary function from Summarise to be used to compute meta-statistical summary information after all the replications have completed within each design condition. Note that unlike the Generate and Analyse steps, the Summarise portion is not as important to perfectly organize as the results can be summarised later on by using the built-in reSummarise function (provided either store_results = TRUE or save_results = TRUE were included).

Omitting this function will return a tibble with the Design and associated results information for all nrow(Design) * repliations evaluations if the results from each Analyse() call was a one-dimensional vector. For more general objects returned by Analyse() (such as lists), a list containing the results returned form Analyse. This is generally only recommended for didactic purposes because the results will leave out a large amount of information (e.g., try-errors, warning messages, saving files, etc), can witness memory related issues if the Analyse function returns larger objects, and generally is not as flexible internally. However, it may be useful when replications are expensive and ANOVA-based decompositions involving the within-condition replication information are of interest, though of course this can be circumvented by using store_results = TRUE or save_results = TRUE with or without a supplied summarise definition.

fixed_objects

(optional) an object (usually a named list) containing additional user-defined objects that should remain fixed across conditions. This is useful when including large vectors/matrices of population parameters, fixed data information that should be used across all conditions and replications (e.g., including a common design matrix for linear regression models), or simply control constant global elements (e.g., a constant for sample size)

packages

a character vector of external packages to be used during the simulation (e.g., c('MASS', 'extraDistr', 'simsem')). Use this input when running code in parallel to use non-standard functions from additional packages, otherwise the functions must be made available by using explicit library or require calls within the provided simulation functions. Alternatively, functions can be called explicitly without attaching the package with the :: operator (e.g., extraDistr::rgumbel())

filename

(optional) the name of the .rds file to save the final simulation results to. If the extension .rds is not included in the file name (e.g. "mysimulation" versus "mysimulation.rds") then the .rds extension will be automatically added to the file name to ensure the file extension is correct.

Note that if the same file name already exists in the working directly at the time of saving then a new file will be generated instead and a warning will be thrown. This helps to avoid accidentally overwriting existing files. Default is NULL, indicating no file will be saved by default

debug

a string indicating where to initiate a browser() call for editing and debugging, and pairs particularly well with the load_seed argument for precise debugging. General options are 'none' (default; no debugging), 'error', which starts the debugger when any error in the code is detected in one of three generate-analyse-summarise functions, and 'all', which debugs all the user defined functions regardless of whether an error was thrown or not. Specific options include: 'generate' to debug the data simulation function, 'analyse' to debug the computational function, and 'summarise' to debug the aggregation function.

If the Analyse argument is supplied as a named list of functions then it is also possible to debug the specific function of interest by passing the name of the respective function in the list. For instance, if analyse = list(A1=Analyse.A1, A2=Analyse.A2) then passing debug = 'A1' will debug only the first function in this list, and all remaining analysis functions will be ignored.

For debugging specific rows in the Design input (e.g., when a number of initial rows successfully complete but the kth row fails) the row number can be appended to the standard debug input using a '-' separator. For instance, debugging whenever an error is raised in the second row of Design can be declared via debug = 'error-2'.

Finally, users may place browser calls within the respective functions for debugging at specific lines, which is useful when debugging based on conditional evaluations (e.g., if(this == 'problem') browser()). Note that parallel computation flags will automatically be disabled when a browser() is detected or when a debugging argument other than 'none' is supplied

load_seed

used to replicate an exact simulation state, which is primarily useful for debugging purposes. Input can be a character object indicating which file to load from when the .Random.seeds have be saved (after a call with save_seeds = TRUE),

or an integer vector indicating the actual .Random.seed values (e.g., extracted after using store_seeds). E.g., load_seed = 'design-row-2/seed-1' will load the first seed in the second row of the design input, or explicitly passing the elements from .Random.seed (see SimExtract to extract the seeds associated explicitly with errors during the simulation, where each column represents a unique seed). If the input is a character vector then it is important NOT to modify the design input object, otherwise the path may not point to the correct saved location, while if the input is an integer vector (or single column tbl object) then it WILL be important to modify the design input in order to load this exact seed for the corresponding design row. Default is NULL

save

logical; save the temporary simulation state to the hard-drive? This is useful for simulations which require an extended amount of time, though for shorter simulations can be disabled to slightly improve computational efficiency. When TRUE, which is the default when evaluating replications > 2, a temp file will be created in the working directory which allows the simulation state to be saved and recovered (in case of power outages, crashes, etc). As well, triggering this flag will save any fatal .Random.seed states when conditions unexpectedly crash (where each seed is stored row-wise in an external .rds file), which provides a much easier mechanism to debug issues (see load_seed for details). Upon completion, this temp file will be removed.

To recover your simulation at the last known location (having patched the issues in the previous execution code) simply re-run the code you used to initially define the simulation and the external file will automatically be detected and read-in. Default is TRUE when replications > 10 and FALSE otherwise

store_results

logical; store the complete tables of simulation results in the returned object? This is TRUE default, though if RAM anticipated to be an issue see save_results instead. Note that if the Design object is omitted from the call to runSimulation(), or the number of rows in Design is exactly 1, then this argument is automatically set to TRUE as RAM storage is no longer an issue.

To extract these results pass the returned object to either SimResults or SimExtract with what = 'results', which will return a named list of all the simulation results for each condition if nrow(Design) > 1; otherwise, if nrow(Design) == 1 or Design was missing the results object will be stored as-is

save_results

logical; save the results returned from Analyse to external .rds files located in the defined save_results_dirname directory/folder? Use this if you would like to keep track of the individual parameters returned from the analysis function. Each saved object will contain a list of three elements containing the condition (row from design), results (as a list or matrix), and try-errors. See SimResults for an example of how to read these .rds files back into R after the simulation is complete. Default is FALSE.

WARNING: saving results to your hard-drive can fill up space very quickly for larger simulations. Be sure to test this option using a smaller number of replications before the full Monte Carlo simulation is performed. See also reSummarise for applying summarise functions from saved simulation results

parallel

logical; use parallel processing from the parallel package over each unique condition? This distributes the independent replications across the defined nodes, and is repeated for each row condition in the design input.

Alternatively, if the future package approach is desired then passing parallel = 'future' to runSimulation() will use the defined plan for execution. This allows for greater flexibility when specifying the general computing plan (e.g., plan(multisession)) for parallel computing on the same machine, plan(future.batchtools::batchtools_slurm) for common MPI/Slurm schedulers, etc). However, it is the responsibility of the user to use plan(sequential) to reset the computing plan when the jobs are completed

ncores

number of cores to be used in parallel execution (ignored if using the future package approach). Default uses all available minus 1

cl

cluster object defined by makeCluster used to run code in parallel (ignored if using the future package approach). If NULL and parallel = TRUE, a local cluster object will be defined which selects the maximum number cores available and will be stopped when the simulation is complete. Note that supplying a cl object will automatically set the parallel argument to TRUE. Define and supply this cluster object yourself whenever you have multiple nodes and can link them together manually

If the future package has been attached prior to executing runSimulation() then the associated plan() will be followed instead

notification

an optional character vector input that can be used to send Pushbullet notifications from a configured computer. This reports information such as the total execution time, the condition completed, and error/warning messages recorded. This arguments assumes that users have already A) registered for a Pushbullet account, B) installed the application on their mobile device and computer, and C) created an associated JSON file of the form ~/.rpushbullet.json using RPushbullet::pbSetup()).

To utilize the RPushbullet in SimDesign first call library(RPushbullet before running runSimulation() to read-in the default JSON file. Next, pass one of the following supported options: 'none' (default; send no notification), 'condition' to send a notification after each condition has completed, or 'complete' to send a notification only when the simulation has finished.

beep

logical; call the beepr package when the simulation is completed?

sound

sound argument passed to beepr::beep()

CI

bootstrap confidence interval level (default is 95%)

seed

a vector or list of integers to be used for reproducibility. The length of the vector must be equal the number of rows in design. If the input is a vector then set.seed or clusterSetRNGStream for each condition will be called, respectively. If a list is provided then these numbers must have been generated from gen_seeds with the argument CMRG.seed used to specify the initial. The list approach ensures random number generation independence across conditions and replications, while the vector input ensures independence within the replications per conditions but not necessarily across conditions. Default randomly generates seeds within the range 1 to 2147483647 for each condition via link{gen_seeds}

boot_method

method for performing non-parametric bootstrap confidence intervals for the respective meta-statistics computed by the Summarise function. Can be 'basic' for the empirical bootstrap CI, 'percentile' for percentile CIs, 'norm' for

> normal approximations CIs, or 'studentized' for Studentized CIs (should only be used for simulations with lower replications due to its computational intensity). Alternatively, CIs can be constructed using the argument 'CLT', which computes the intervals according to the large-sample standard error approximation $SD(results)/\sqrt{R}$. Default is 'none', which performs no CI computations

boot_draws

number of non-parametric bootstrap draws to sample for the summarise function after the generate-analyse replications are collected. Default is 1000

max_errors

the simulation will terminate when more than this number of consecutive errors are thrown in any given condition, causing the simulation to continue to the next unique design condition. This is included to avoid getting stuck in infinite redraws, and to indicate that something fatally problematic is going wrong in the generate-analyse phases. Default is 50

resume

logical; if a temporary SimDesign file is detected should the simulation resume from this location? Keeping this TRUE is generally recommended, however this should be disabled if using runSimulation within runSimulation to avoid reading improper save states. Alternatively, if an integer is supplied then the simulation will continue at the associated row location in design (e.g., resume=10). This is useful to overwrite a previously evaluate element in the temporary files that was detected to contain fatal errors that require re-evaluation without discarding the originally valid rows in the simulation

save_details

a list pertaining to information regarding how and where files should be saved when the save or save_results flags are triggered.

- safe logical; trigger whether safe-saving should be performed. When TRUE files will never be overwritten accidentally, and where appropriate the program will either stop or generate new files with unique names. Default is **TRUE**
- compname name of the computer running the simulation. Normally this doesn't need to be modified, but in the event that a manual node breaks down while running a simulation the results from the temp files may be resumed on another computer by changing the name of the node to match the broken computer. Default is the result of evaluating unname(Sys.info()['nodename'])
- out_rootdir root directory to save all files to. Default uses the current working directory
- save_results_dirname a string indicating the name of the folder to save result objects to when save_results = TRUE. If a directory/folder does not exist in the current working directory then a unique one will be created automatically. Default is 'SimDesign-results_' with the associated compname appended if no filename is defined, otherwise the filename is used to replace 'SimDesign' in the string
- save_results_filename a string indicating the name file to store, where the Design row ID will be appended to ensure uniqueness across rows. Specifying this input will disable any checking for the uniqueness of the file folder, thereby allowing independent runSimulation calls to write to the same save_results_dirname. Useful when the files should all be stored in the same working directory, however the rows of Design are evaluated in isolation (e.g., for HPC structures that allow asynchronous file storage).

WARNING: the uniqueness of the file names are not checked using this approach, therefore please ensure that each generated name will be unique a priori, such as naming the file based on the supplied row condition information

save_seeds_dirname a string indicating the name of the folder to save . Random. seed
 objects to when save_seeds = TRUE. If a directory/folder does not exist in
 the current working directory then one will be created automatically. Default is 'SimDesign-seeds_' with the associated compname appended if no
 filename is defined, otherwise the filename is used to replace 'SimDesign'
 in the string

control

a list for extra information flags for controlling less commonly used features. These include

stop_on_fatal logical (default is FALSE); should the simulation be terminated immediately when the maximum number of consecutive errors (max_errors) is reached? If FALSE, the simulation will continue as though errors did not occur, however a column FATAL_TERMINATION will be included in the resulting object indicating the final error message observed, and NA placeholders will be placed in all other row-elements. Default is FALSE

warnings_as_errors logical (default is FALSE); treat warning messages as error messages during the simulation? Default is FALSE, therefore warnings are only collected and not used to restart the data generation step, and the seeds associated with the warning message conditions are not stored within the final simulation object.

Note that this argument is generally intended for debugging/early planning stages when designing a simulation experiment. If specific warnings are known to be problematic and should be treated as errors then please use convertWarnings instead

save_seeds logical; save the .Random.seed states prior to performing each replication into plain text files located in the defined save_seeds_dirname directory/folder? Use this if you would like to keep track of every simulation state within each replication and design condition. This can be used to completely replicate any cell in the simulation if need be. As well, see the load_seed input to load a given .Random.seed to exactly replicate the generated data and analysis state (mostly useful for debugging). When TRUE, temporary files will also be saved to the working directory (in the same way as when save = TRUE). Default is FALSE

Note, however, that this option is not typically necessary or recommended since the .Random. seed states for simulation replications that throw errors during the execution are automatically stored within the final simulation object, and can be extracted and investigated using SimExtract. Hence, this option is only of interest when *all* of the replications must be reproducible (which occurs very rarely), otherwise the defaults to runSimulation should be sufficient

store_Random.seeds logical; store the complete .Random.seed states for each
simulation replicate? Default is FALSE as this can take up a great deal of
unnecessary RAM (see related save_seeds), however this may be useful
when used with runArraySimulation. To extract use SimExtract(...,
what = 'stored_Random.seeds')

store_warning_seeds logical (default is FALSE); in addition to storing the .Random.seed states whenever error messages are raised, also store the .Random.seed states when warnings are raised? This is disabled by default since warnings are generally less problematic than errors, and because many more warnings messages may be raised throughout the simulation (potentially causing RAM related issues when constructing the final simulation object as any given simulation replicate could generate numerous warnings, and storing the seeds states could add up quickly).

Set this to TRUE when replicating warning messages is important, however be aware that too many warnings messages raised during the simulation implementation could cause RAM related issues.

- include_replication_index **or** include_reps logical (default is FALSE); should a REPLICATION element be added to the condition object when performing the simulation to track which specific replication experiment is being evaluated? This is useful when, for instance, attempting to run external software programs (e.g., Mplus) that require saving temporary data sets to the hard-drive (see the Wiki for examples)
- try_all_analyse logical; when analyse is a list, should every generated data set be analyzed by each function definition in the analyse list? Default is TRUE.

Note that this TRUE default can be computationally demanding when some analysis functions require more computational resources than others, and the data should be discarded early as an invalid candidate (e.g., estimating a model via maximum-likelihood in on analyze component, while estimating a model using MCMC estimation on another). Hence, the main benefit of using FALSE instead is that the data set may be rejected earlier, where easier/faster to estimate analyse definitions should be placed earlier in the list as the functions are evaluated in sequence (e.g., Analyse = list(MLE=MLE_definition, MCMC=MCMC_definition))

- allow_na logical (default is FALSE); should NAs be allowed in the analyse step as a valid result from the simulation analysis?
- allow_nan logical (default is FALSE); should NaNs be allowed in the analyse step as a valid result from the simulation analysis?
- type default type of cluster to create for the cl object if no supplied. For Windows OS this defaults to "PSOCK", otherwise "SOCK" is selected (suitable for Linux and Mac OSX). This is ignored if the user specifies their own cl object
- print_RAM logical (default is TRUE); print the amount of RAM used throughout the simulation? Set to FALSE if unnecessary or if the call to gc is unnecessarily time consuming
- max_time Similar to runArraySimulation, specifies the (approximate) maximum time that the simulation is allowed to be executed. However, unlike the implementation in runArraySimulation is evaluated on a per condition basis, where max_time is only evaluated after every row in the design object has been completed (hence, is notably more approximate as it has the potential to overshoot by a wider margin). Default sets no time limit. See runArraySimulation for the input specifications.

max_RAM Similar to runArraySimulation, specifies the (approximate) maximum RAM that the simulation is allowed to occupy. However, unlike the implementation in runArraySimulation is evaluated on a per condition basis, where max_RAM is only evaluated after every row in the design object has been completed (hence, is notably more approximate as it has the potential to overshoot by a wider margin). Default sets no RAM limit. See runArraySimulation for the input specifications.

progress logical; display a progress bar (using the pbapply package) for each simulation

condition? This is useful when simulations conditions take a long time to run

(see also the notifications argument). Default is TRUE

verbose logical; print messages to the R console? Default is TRUE

object SimDesign object returned from runSimulation

... additional arguments

x SimDesign object returned from runSimulation

list2char logical; for tibble object re-evaluate list elements as character vectors for better

printing of the levels? Note that this does not change the original classes of the

object, just how they are printed. Default is TRUE

Details

For an in-depth tutorial of the package please refer to Chalmers and Adkins (2020; doi:10.20982/tqmp.16.4.p248). For an earlier didactic presentation of the package refer to Sigal and Chalmers (2016; doi:10.1080/10691898.2016.1246953). Finally, see the associated wiki on Github (https://github.com/philchalmers/SimDesign/wiki) for tutorial material, examples, and applications of SimDesign to real-world simulation experiments, as well as the various vignette files associated with the package.

The strategy for organizing the Monte Carlo simulation work-flow is to

- 1) Define a suitable Design object (a tibble or data.frame) containing fixed conditional information about the Monte Carlo simulations. Each row or this design object pertains to a unique set of simulation to study, while each column the simulation factor under investigation (e.g., sample size, distribution types, etc). This is often expedited by using the createDesign function, and if necessary the argument subset can be used to remove redundant or non-applicable rows
- 2) Define the three step functions to generate the data (Generate; see also https://CRAN.R-project.org/view=Distributions for a list of distributions in R), analyse the generated data by computing the respective parameter estimates, detection rates, etc (Analyse), and finally summarise the results across the total number of replications (Summarise).
- 3) Pass the design object and three defined R functions to runSimulation, and declare the number of replications to perform with the replications input. This function will return a suitable tibble object with the complete simulation results and execution details
- **4**) Analyze the output from runSimulation, possibly using ANOVA techniques (SimAnova) and generating suitable plots and tables

Expressing the above more succinctly, the functions to be called have the following form, with the exact functional arguments listed:

```
Design <- createDesign(...)
Generate <- function(condition, fixed_objects = NULL) {...}
Analyse <- function(condition, dat, fixed_objects = NULL) {...}
Summarise <- function(condition, results, fixed_objects = NULL) {...}
res <- runSimulation(design=Design, replications, generate=Generate, analyse=Analyse, summarise=Summar</pre>
```

The condition object above represents a single row from the design object, indicating a unique Monte Carlo simulation condition. The condition object also contains two additional elements to help track the simulation's state: an ID variable, indicating the respective row number in the design object, and a REPLICATION element indicating the replication iteration number (an integer value between 1 and replication). This setup allows users to easily locate the rth replication (e.g., REPLICATION == 500) within the jth row in the simulation design (e.g., ID == 2). The REPLICATION input is also useful when temporarily saving files to the hard-drive when calling external command line utilities (see examples on the wiki).

For a template-based version of the work-flow, which is often useful when initially defining a simulation, use the SimFunctions function. This function will write a template simulation to one/two files so that modifying the required functions and objects can begin immediately. This means that users can focus on their Monte Carlo simulation details right away rather than worrying about the repetitive administrative code-work required to organize the simulation's execution flow.

Finally, examples, presentation files, and tutorials can be found on the package wiki located at https://github.com/philchalmers/SimDesign/wiki.

Value

a tibble from the dplyr package (also of class 'SimDesign') with the original design conditions in the left-most columns, simulation results in the middle columns, and additional information in the right-most columns (see below).

The right-most column information for each condition are: REPLICATIONS to indicate the number of Monte Carlo replications, SIM_TIME to indicate how long (in seconds) it took to complete all the Monte Carlo replications for each respective design condition, RAM_USED amount of RAM that was in use at the time of completing each simulation condition, COMPLETED to indicate the date in which the given simulation condition completed, SEED for the integer values in the seed argument (if applicable; not relevant when L'Ecuyer-CMRG method used), and, if applicable, ERRORS and WARNINGS which contain counts for the number of error or warning messages that were caught (if no errors/warnings were observed these columns will be omitted). Note that to extract the specific error and warnings messages see SimExtract. Finally, if boot_method was a valid input other than 'none' then the final right-most columns will contain the labels BOOT_ followed by the name of the associated meta-statistic defined in summarise() and and bootstrapped confidence interval location for the meta-statistics.

Saving data, results, seeds, and the simulation state

To conserve RAM, temporary objects (such as data generated across conditions and replications) are discarded; however, these can be saved to the hard-disk by passing the appropriate flags. For longer simulations it is recommended to use the save_results flag to write the analysis results to the hard-drive.

The use of the store_seeds or the save_seeds options can be evoked to save R's .Random.seed state to allow for complete reproducibility of each replication within each condition. These individual .Random.seed terms can then be read in with the load_seed input to reproduce the exact simulation state at any given replication. Most often though, saving the complete list of seeds is unnecessary as problematic seeds are automatically stored in the final simulation object to allow for easier replicability of potentially problematic errors (which incidentally can be extracted using SimExtract(res, 'error_seeds') and passed to the load_seed argument). Finally, providing a vector of seeds is also possible to ensure that each simulation condition is macro reproducible under the single/multi-core method selected.

Finally, when the Monte Carlo simulation is complete it is recommended to write the results to a hard-drive for safe keeping, particularly with the filename argument provided (for reasons that are more obvious in the parallel computation descriptions below). Using the filename argument supplied is safer than using, for instance, saveRDS directly because files will never accidentally be overwritten, and instead a new file name will be created when a conflict arises; this type of implementation safety is prevalent in many locations in the package to help avoid unrecoverable (yet surprisingly common) mistakes during the process of designing and executing Monte Carlo simulations.

Resuming temporary results

In the event of a computer crash, power outage, etc, if save = TRUE was used (the default) then the original code used to execute runSimulation() need only be re-run to resume the simulation. The saved temp file will be read into the function automatically, and the simulation will continue one the condition where it left off before the simulation state was terminated. If users wish to remove this temporary simulation state entirely so as to start anew then simply pass SimClean(temp = TRUE) in the R console to remove any previously saved temporary objects.

A note on parallel computing

When running simulations in parallel (either with parallel = TRUE or when using the future approach with a plan() other than sequential) R objects defined in the global environment will generally not be visible across nodes. Hence, you may see errors such as Error: object 'something' not found if you try to use an object that is defined in the work space but is not passed to runSimulation. To avoid this type or error, simply pass additional objects to the fixed_objects input (usually it's convenient to supply a named list of these objects). Fortunately, however, custom functions defined in the global environment are exported across nodes automatically. This makes it convenient when writing code because custom functions will always be available across nodes if they are visible in the R work space. As well, note the packages input to declare packages which must be loaded via library() in order to make specific non-standard R functions available across nodes.

rValeMaurelli

Generate non-normal data with Vale & Maurelli's (1983) method

Description

Generate multivariate non-normal distributions using the third-order polynomial method described by Vale & Maurelli (1983). If only a single variable is generated then this function is equivalent to the method described by Fleishman (1978).

Usage

```
rValeMaurelli(
   n,
   mean = rep(0, nrow(sigma)),
   sigma = diag(length(mean)),
   skew = rep(0, nrow(sigma)),
   kurt = rep(0, nrow(sigma)))
```

Arguments

n	number of samples to draw
mean	a vector of k elements for the mean of the variables
sigma	desired k x k covariance matrix between bivariate non-normal variables
skew	a vector of k elements for the skewness of the variables
kurt	a vector of k elements for the kurtosis of the variables

sk <- c(1.5,1.5,0.5)
ku <- c(3.75,3.5,0.5)

nonnormal <- rValeMaurelli(n, sigma=cor, skew=sk, kurt=ku)
# cor(nonnormal)
# psych::describe(nonnormal)</pre>
```

Serlin2000

Empirical detection robustness method suggested by Serlin (2000)

Description

Hypothesis test to determine whether an observed empirical detection rate, coupled with a given robustness interval, statistically differs from the population value. Uses the methods described by Serlin (2000) as well to generate critical values (similar to confidence intervals, but define a fixed window of robustness). Critical values may be computed without performing the simulation experiment (hence, can be obtained a priori).

Usage

```
Serlin2000(p, alpha, delta, R, CI = 0.95)
```

102 Serlin2000

Arguments

p	(optional) a vector containing the empirical detection rate(s) to be tested. Omitting this input will compute only the CV1 and CV2 values, while including this input will perform a one-sided hypothesis test for robustness
alpha	Type I error rate (e.g., often set to .05)
delta	(optional) symmetric robustness interval around alpha (e.g., a value of .01 when alpha = $.05$ would test the robustness window .0406)
R	number of replications used in the simulation
CI	confidence interval for alpha as a proportion. Default of 0.95 indicates a 95% interval

Examples

```
# Cochran's criteria at alpha = .05 (i.e., 0.5 +- .01), assuming N = 2000 Serlin2000(p = .051, alpha = .05, delta = .01, R = 2000)

# Bradley's liberal criteria given p = .06 and .076, assuming N = 1000 Serlin2000(p = .060, alpha = .05, delta = .025, R = 1000)

Serlin2000(p = .076, alpha = .05, delta = .025, R = 1000)

# multiple p-values
Serlin2000(p = c(.05, .06, .07), alpha = .05, delta = .025, R = 1000)

# CV values computed before simulation performed
Serlin2000(alpha = .05, R = 2500)
```

SFA

Surrogate Function Approximation via the Generalized Linear Model

Description

Given a simulation that was executed with runSimulation, potentially with the argument store_results = TRUE to store the unsummarised analysis results, fit a surrogate function approximation (SFA) model to the results and (optionally) perform a root-solving step to solve a target quantity. See Schoemann et al. (2014) for details.

Usage

```
SFA(
   results,
   formula,
   family = "binomial",
   b = NULL,
   design = NULL,
   CI = 0.95,
   interval = NULL,
   ...
)

## S3 method for class 'SFA'
print(x, ...)
```

Arguments

results	data returned from runSimulation. This can be the original results object or the extracted results stored when using store_results = TRUE included to store the analysis results.
formula	formula to specify for the regression model
family	character vector indicating the family of GLMs to use (see family)
b	(optional) Target quantity to use for root solving given the fitted surrogate function (e.g., find sample size associated with SFA implied power of .80)
design	(optional) data. frame object containing all the information relevant for the surrogate model (passed to newdata in predict) with an NA value in the variable to be solved
CI	advertised confidence interval of SFA prediction around solved target
interval	interval to be passed to uniroot if not specified then the lowest and highest values from results for the respective variable will be used
	additional arguments to pass to glm
X	an object of class SFA

SimAnova

Function for decomposing the simulation into ANOVA-based effect sizes

Description

Given the results from a simulation with runSimulation form an ANOVA table (without p-values) with effect sizes based on the eta-squared statistic. These results provide approximate indications of observable simulation effects, therefore these ANOVA-based results are generally useful as exploratory rather than inferential tools.

Usage

```
SimAnova(formula, dat, subset = NULL, rates = TRUE)
```

108 SimCheck

Arguments

an R formula generally of a form suitable for 1m or aov. However, if the dependent variable (left size of the equation) is omitted then all the dependent variables in the simulation will be used and the result will return a list of analyses

dat an object returned from runSimulation of class 'SimDesign'

subset an optional argument to be passed to subset with the same name. Used to subset

the results object while preserving the associated attributes

rates logical; does the dependent variable consist of rates (e.g., returned from ECR or

EDR)? Default is TRUE, which will use the logit of the DV to help stabilize the proportion-based summary statistics when computing the parameters and effect

sizes

Sigal, M. J., & Chalmers, R. P. (2016). Play it again: Teaching statistics with Monte Carlo simulation. Journal of Statistics Education, 24(3), 136-156. doi:10.1080/10691898.2016.1246953

Examples

```
data(BF_sim)
# all results (not usually good to mix Power and Type I results together)
SimAnova(alpha.05.F ~ (groups_equal + distribution)^2, BF_sim)
# only use anova for Type I error conditions
SimAnova(alpha.05.F ~ (groups_equal + distribution)^2, BF_sim, subset = var_ratio == 1)
# run all DVs at once using the same formula
SimAnova(~ groups_equal * distribution, BF_sim, subset = var_ratio == 1)
```

SimCheck 109

Description

This function reads the temporary file saved by runSimulation by collapsing the information into a suitable (albeit temporary) object of class 'SimDesign'. This is useful when taking a quick-peak at how the early simulation results are performing (useful long running simulation results with many rows in the Design object). Returns a tibble-based data frame object (tbl_df).

Usage

```
SimCheck(file)
```

Arguments

file

the temp file currently saving the simulation state. If missing the file is assumed to be in the current working directory, and start with the name 'SIMDESIGN-TEMPFILE'

110 SimClean

Removes/cleans files and folders that have been saved

Description

This function is mainly used in pilot studies where results and datasets have been temporarily saved by runSimulation but should be removed before beginning the full Monte Carlo simulation (e.g., remove files and folders which contained bugs/biased results).

Usage

```
SimClean(
    ...,
    dirs = NULL,
    temp = TRUE,
    results = FALSE,
    seeds = FALSE,
    save_details = list()
)
```

Arguments

	one or more character objects indicating which files to remove. Used to remove .rds files which were saved with saveRDS or when using the save and filename inputs to runSimulation
dirs	a character vector indicating which directories to remove
temp	logical; remove the temporary file saved when passing save = TRUE?
results	logical; remove the .rds results files saved when passing save_results = TRUE?
seeds	logical; remove the seed files saved when passing save_seeds = TRUE?
save_details	a list pertaining to information about how and where files were saved (see the corresponding list in runSimulation)

SimDesign

Structure for Organizing Monte Carlo Simulation Designs

Description

Structure for Organizing Monte Carlo Simulation Designs

Details

Provides tools to help organize Monte Carlo simulations in R. The package controls the structure and back-end of Monte Carlo simulations by utilizing a general generate-analyse-summarise strategy. The functions provided control common simulation issues such as re-simulating non-convergent results, support parallel back-end computations with proper random number generation within each simulation condition, save and restore temporary files, aggregate results across independent nodes, and provide native support for debugging. The primary function for organizing the simulations is runSimulation, while for array jobs submitting to HPC clusters (e.g., SLURM) see runArraySimulation and the associated package vignettes.

For an in-depth tutorial of the package please refer to Chalmers and Adkins (2020; doi:10.20982/tqmp.16.4.p248). For an earlier didactic presentation of the package users can refer to Sigal and Chalmers (2016; doi:10.1080/10691898.2016.1246953). Finally, see the associated wiki on Github (https://github.com/philchalmers/SimDesign/wiki) for other tutorial material, examples, and applications of SimDesign to real-world simulations.

112 SimExtract

References

Chalmers, R. P., & Adkins, M. C. (2020). Writing Effective and Reliable Monte Carlo Simulations with the SimDesign Package. The Quantitative Methods for Psychology, 16(4), 248-280. doi:10.20982/tqmp.16.4.p248

Sigal, M. J., & Chalmers, R. P. (2016). Play it again: Teaching statistics with Monte Carlo simulation. Journal of Statistics Education, 24(3), 136-156. doi:10.1080/10691898.2016.1246953

SimExtract

Function to extract extra information from SimDesign objects

Description

Function used to extract any error or warnings messages, the seeds associated with any error or warning messages, and any analysis results that were stored in the final simulation object.

Usage

```
SimExtract(object, what, fuzzy = TRUE)
```

Arguments

object

object returned from runSimulation

what

character indicating what information to extract. Possible inputs include 'errors' to return a tibble object containing counts of any error messages, 'warnings' to return a data.frame object containing counts of any warning messages, 'seeds' for the specified random number generation seeds, 'Random.seeds' for the complete list of .Random.seed states across replications (only stored when runSimulation(..., control = list(store_Random.seeds=TRUE))), 'error_seeds' and 'warning_seeds' to extract the associated .Random.seed values associated with the ERROR/WARNING messages, 'results' to extract the simulation results if the option store_results was passed to runSimulation, 'filename' and 'save_results_dirname' for extracting the saved file/directory name information (if used), and 'summarise' if the Summarise definition returned a named list rather than a named numeric vector.

Note that 'warning_seeds' are not stored automatically in simulations and require passing store_warning_seeds = TRUE to runSimulation.

logical; use fuzzy string matching to reduce effectively identical messages? For example, when attempting to invert a matrix the error message "System is computationally singular: reciprocal condition number = 1.92747e-17" and "System is computationally singular: reciprocal condition number = 2.15321e-16" are effectively the same, and likely should be reported in the same columns of the extracted output

114 SimFunctions

SimFunctions	Template-based generation of the Generate-Analyse-Summarise func-
	tions

Description

This function prints template versions of the required Design and Generate-Analyse-Summarise functions for SimDesign to run simulations. Templated output comes complete with the correct inputs, class of outputs, and optional comments to help with the initial definitions. Use this at the start of your Monte Carlo simulation study. Following the definition of the SimDesign template file please refer to detailed the information in runSimulation for how to edit this template to make a working simulation study.

Usage

```
SimFunctions(
   filename = NULL,
   dir = getwd(),
   save_structure = "single",
   extra_file = FALSE,
   nAnalyses = 1,
   nGenerate = 1,
   summarise = TRUE,
   comments = FALSE,
   openFiles = TRUE,
   spin_header = TRUE,
   SimSolve = FALSE
)
```

Arguments

filename a character vector indicating whether the output should be saved to two respec-

tive files containing the simulation design and the functional components, respectively. Using this option is generally the recommended approach when be-

ginning to write a Monte Carlo simulation

dir the directory to write the files to. Default is the working directory

save_structure character indicating the number of files to break the simulation code into when

filename is included (default is 'single' for one file). When save_structure = 'double' the output is saved to two separate files containing the functions and design definitions, and when save_structure = 'all' the generate, analyse, summarise, and execution code area all saved into separate files. The purpose for this structure is because multiple structured files often makes organization and debugging slightly easier larger Monte Carlo simulations, though in principle all

files could be stored into a single R script

extra_file logical; should and extra file be saved containing user-defined functions or ob-

jects? Default is FALSE

SimFunctions 115

nAnalyses number of analysis functions to create (default is 1). Increasing the value of

this argument when independent analysis are being performed allows function

definitions to be better partitioned and potentially more modular

nGenerate number of generate functions to create (default is 1). Increase the value of this

argument when when the data generation functions are very different and should be isolated from each other (otherwise, if there is much in common between the generate steps, the default of 1 should be preferred). Otherwise, if nGenerate == 0 then no generate function will be provided and instead this data-generation step can be defined in the analysis function(s) (only recommended for smaller

simulations)

summarise include summarise function? Default is TRUE

comments logical; include helpful comments? Default is FALSE

openFiles logical; after files have been generated, open them in your text editor (e.g., if

Rstudio is running the scripts will open in a new tab)?

spin_header logical; include a basic knitr::spin header to allow the simulation to be knit-

ted? Default is TRUE. For those less familiar with spin documents see https://bookdown.org/yihui/rn

for further details

SimSolve logical; should the template be generated that is intended for a SimSolve imple-

mentation? Default is FALSE

Details

The recommended approach to organizing Monte Carlo simulation files is to first save the template generated by this function to the hard-drive by passing a suitable filename argument (which, if users are interacting with R via the RStudio IDE, will also open the template file after it has been saved). For larger simulations, two separate files could also be used (achieved by changing out.files), and may be easier for debugging/sourcing the simulation code; however, this is a matter of preference and does not change any functionality in the package.

runSimulation

116 SimResults

Examples

SimResults

Function to read in saved simulation results

Description

If runSimulation was passed the flag save_results = TRUE then the row results corresponding to the design object will be stored to a suitable sub-directory as individual .rds files. While users could use readRDS directly to read these files in themselves, this convenience function will read the desired rows in automatically given the returned object from the simulation. Can be used to read in 1 or more .rds files at once (if more than 1 file is read in then the result will be stored in a list).

Usage

```
SimResults(obj, which, prefix = "results-row", wd = getwd())
```

Arguments

obj	object returned from runSimulation where save_results = TRUE or store_results
	was used. If the former then the remaining function arguments can be useful for
	reading in specific files
which	a numeric vector indicating which rows should be read in. If missing, all rows will be read in

SimResults 117

prefix character indicating prefix used for stored files wd working directory; default is found with getwd.

Value

the returned result is either a nested list (when length(which) > 1) or a single list (when length(which) == 1) containing the simulation results. Each read-in result refers to a list of 4 elements:

condition the associate row (ID) and conditions from the respective design object

results the object with returned from the analyse function, potentially simplified into a matrix or data.frame

errors a table containing the message and number of errors that caused the generate-analyse steps to be rerun. These should be inspected carefully as they could indicate validity issues with the simulation that should be noted

warnings a table containing the message and number of non-fatal warnings which arose from the analyse step. These should be inspected carefully as they could indicate validity issues with the simulation that should be noted

118 SimShiny

```
## End(Not run)
```

SimShiny

Generate a basic Monte Carlo simulation GUI template

Description

This function generates suitable stand-alone code from the shiny package to create simple web-interfaces for performing single condition Monte Carlo simulations. The template generated is relatively minimalistic, but allows the user to quickly and easily edit the saved files to customize the associated shiny elements as they see fit.

Usage

```
SimShiny(filename = NULL, dir = getwd(), design, ...)
```

Arguments

filename	an optional name of a text file to save the server and UI components (e.g., 'mysimGUI.R'). If omitted, the code will be printed to the R console instead
dir	the directory to write the files to. Default is the working directory
design	design object from runSimulation
• • •	arguments to be passed to runSimulation. Note that the design object is not used directly, and instead provides options to be selected in the GUI

SimSolve

One Dimensional Root (Zero) Finding in Simulation Experiments

Description

This function provides a stochastic root-finding approach to solving specific quantities in simulation experiments (e.g., solving for a specific sample size to meet a target power rate) using the Probablistic Bisection Algorithm with Bolstering and Interpolations (ProBABLI; Chalmers, in review). The structure follows the steps outlined in runSimulation, however portions of the design input are taken as variables to be estimated rather than fixed, and the constant b is required in order to solve the root equation f(x) - b = 0.

Usage

```
SimSolve(
  design,
  interval,
  b,
  generate,
  analyse,
  summarise,

## S3 method for class 'SimSolve'
summary(object, tab.only = FALSE, reps.cutoff = 300, ...)
## S3 method for class 'SimSolve'
plot(x, y, ...)
```

Arguments

design a tibble or data.frame object containing the Monte Carlo simulation con-

ditions to be studied, where each row represents a unique condition and each column a factor to be varied (see also createDesign). However, exactly one column of this object must be specified with NA placeholders to indicate that the

missing value should be solved via the stochastic optimizer

interval a vector of length two, or matrix with nrow(design) and two columns, contain-

ing the end-points of the interval to be searched. If a vector then the interval will

be used for all rows in the supplied design object

b a single constant used to solve the root equation f(x) - b = 0

generate generate function. See runSimulation analyse analysis function. See runSimulation

summarise summary function that returns a single number corresponding to a function eval-

uation f(x) in the equation f(x) = b to be solved as a root f(x) - b = 0. Unlike in the standard runSimulation() definitions this input is required. For further

information on this function specification, see runSimulation

replications a named list or vector indicating the number of replication to use for each de-

sign condition per PBA iteration. By default the input is a list with the arguments burnin.iter = 15L, specifying the number of burn-in iterations to used, burnin.reps = 100L to indicate how many replications to use in each burn-in iteration, max.reps = 500L to prevent the replications from increasing higher than this number, min.total.reps = 9000L to avoid termination when very few replications have been explored (lower bound of the replication budget), and increase.by = 10L to indicate how many replications to increase after the burn-in stage. Unless otherwise specified these defaults will be used, but can be overwritten by explicit definition (e.g., replications = list(increase.by =

25L))

Vector inputs can specify the exact replications for each iterations. As a general rule, early iterations should be relatively low for initial searches to avoid unnecessary computations for locating the approximate root, though the number of replications should gradually increase to reduce the sampling variability as the

PBA approaches the root.

integer logical; should the values of the root be considered integer or numeric? If TRUE

then bolstered directional decisions will be made in the pba function based on

the collected sampling history throughout the search

formula regression formula to use when interpolate = TRUE. Default fits an orthogonal

polynomial of degree 2

family

family argument passed to glm. By default the 'binomial' family is used, as this function defaults to power analysis setups where isolated results passed to summarise will return 0/1s, however other families should be used had summarise returned something else (e.g., if solving for a particular standard error then a 'gaussian' family would be more appropriate).

Note that if individual results from the analyse steps should not be used (i.e., only the aggregate from summarise is meaningful) then set control = list(summarise.reg_data = TRUE) to override the default behaviour, thereby using only the aggregate information and weights

parallel

for parallel computing for slower simulation experiments (see runSimulation for details)

cl

see runSimulation

save

logical; store temporary file in case of crashes. If detected in the working directory will automatically be loaded to resume (see runSimulation for similar behaviour)

resume

logical; if a temporary SimDesign file is detected should the simulation resume from this location? Keeping this TRUE is generally recommended, however this should be disabled if using SimSolve within runSimulation to avoid reading improper save states

method

optimizer method to use. Default is the stochastic root-finder 'ProBABLI', but can also be the deterministic options 'Brent' (which uses the function uniroot) or 'bisection' (for the classical bisection method). If using deterministic root-finders then replications must either equal a single constant to reflect the number of replication to use per deterministic iteration or be a vector of length maxiter to indicate the replications to use per iteration

wait.time

(optional) argument passed to PBA to indicate the time to wait (specified in minutes) per row in the Design object rather than using pre-determined termination criteria based on the estimates. For example, if three three conditions were defined in Design, and wait.time=5, then the total search time till terminate after 15 minutes regardless of independently specified termination criteria in control. Note that maxiter is still used alongside wait.time, therefore this should be increased as well (e.g., to maxiter = 1000)

- tol tolerance criteria for early termination (.1 for integer = TRUE searches; .00025 for non-integer searches
- rel.tol relative tolerance criteria for early termination (default .0001)
- k.success number of consecutive tolerance success given rel.tol and tol criteria. Consecutive failures add -1 to the counter (default is 3)
- bolster logical; should the PBA evaluations use bolstering based on previous evaluations? Default is TRUE, though only applicable when integer = TRUE
- interpolate.R number of replications to collect prior to performing the interpolation step (default is 3000 after accounting for data exclusion from burnin.iter). Setting this to 0 will disable any interpolation computations
- include_reps logical; include a column in the condition elements to indicate how many replications are currently being evaluated? Mainly useful when

further precision tuning within each ProBABLI iteration is desirable (e.g., for bootstrapping). Default is FALSE

summarise.reg_data logical; should the aggregate results from Summarise (along with its associated weights) be used for the interpolation steps, or the raw data from the Analyse step? Set this to TRUE when the individual results from Analyse give less meaningful information

ncores see runSimulation

type type of cluster object to define. If type used in plot then can be 'density' to

plot the density of the iteration history after the burn-in stage, 'iterations' for a bubble plot with inverse replication weights. If not specified then the default

PBA plots are provided (see PBA)

maxiter the maximum number of iterations (default 100)

check.interval logical; should an initial check be made to determine whether f(interval[1L])

and f(interval[2L]) have opposite signs? If FALSE, the specified interval is assumed to contain a root, where f(interval[1]) < 0 and f(interval[2])

> 0. Default is TRUE

verbose logical; print information to the console?

control a list of the algorithm control parameters. If not specified, the defaults de-

scribed below are used.

predCI advertised confidence interval probability for final model-based prediction of

target b given the root input estimate. Returned as an element in the summary()

list output

. . . additional arguments to be pasted to PBA

object of class 'SimSolve'

tab.only logical; print only the (reduce) table of estimates?

reps.cutoff integer indicating the rows to omit from output if the number of replications do

no reach this value

x object of class 'SimSolve'

y design row to plot. If omitted defaults to 1

Details

Root finding is performed using a progressively bolstered version of the probabilistic bisection algorithm (PBA) to find the associated root given the noisy simulation objective function evaluations. Information is collected throughout the search to make more accurate predictions about the associated root via interpolation. If interpolations fail, then the last iteration of the PBA search is returned as the best guess.

Value

the filled-in design object containing the associated lower and upper interval estimates from the stochastic optimization

## A Priori Power Analysis
###################################
# GOAL: Find specific sample size in each group for independent t-test
# corresponding to a power rate of .8
# For ease of the setup, assume the groups are the same size, and the mean
# difference corresponds to Cohen's d values of .2, .5, and .8
# This example can be solved numerically using the pwr package (see below),
# though the following simulation setup is far more general and can be
# used for any generate-analyse combination of interest
# SimFunctions(SimSolve=TRUE)
#### Step 1 --- Define your conditions under study and create design data.frame.
#### However, use NA placeholder for sample size as it must be solved,
#### and add desired power rate to object
Design <- createDesign(N = NA,</pre>
                        d = c(.2, .5, .8),
                        sig.level = .05)
Design
          # solve for NA's
#### Step 2 --- Define generate, analyse, and summarise functions
Generate <- function(condition, fixed_objects = NULL) {</pre>
    Attach(condition)
    group1 <- rnorm(N)</pre>
    group2 <- rnorm(N, mean=d)</pre>
    dat <- data.frame(group = gl(2, N, labels=c('G1', 'G2')),</pre>
                       DV = c(group1, group2))
    dat
}
Analyse <- function(condition, dat, fixed_objects = NULL) {</pre>
    p <- t.test(DV ~ group, dat, var.equal=TRUE)$p.value</pre>
```

```
}
Summarise <- function(condition, results, fixed_objects = NULL) {</pre>
    \# Must return a single number corresponding to f(x) in the
    \# root equation f(x) = b
    ret <- c(power = EDR(results, alpha = condition$sig.level))</pre>
    ret
}
#### Step 3 --- Optimize N over the rows in design
### (For debugging) may want to see if simulation code works as intended first
### for some given set of inputs
# runSimulation(design=createDesign(N=100, d=.8, sig.level=.05),
               replications=10, generate=Generate, analyse=Analyse,
#
#
               summarise=Summarise)

## End(Not run)
```

Summarise

Summarise simulated data using various population comparison statistics

Description

This collapses the simulation results within each condition to composite estimates such as RMSE, bias, Type I error rates, coverage rates, etc. See the See Also section below for useful functions to be used within Summarise.

Usage

```
Summarise(condition, results, fixed_objects = NULL)
```

Summarise 129

Arguments

condition a single row from the design input from runSimulation (as a data.frame),

indicating the simulation conditions

results a tibble data frame (if Analyse returned a named numeric vector of any length)

or a list (if Analyse returned a list or multi-rowed data.frame) containing the analysis results from Analyse, where each cell is stored in a unique row/list

element

fixed_objects object passed down from runSimulation

Value

for best results should return a named numeric vector or data.frame with the desired metasimulation results. Named list objects can also be returned, however the subsequent results must be extracted via SimExtract
